normal rhythm of 70 to 80 per minute the pulse may often be found to fall progressively over days or weeks to 50 or fewer beats per minute With the bradycardia is *associated a similar but less striking fall in the* respiration rate

The mental state is often characteristic It is best defined as one of irritable drowsiness Left alone the patient will remain quiet for hours together with eyes closed only rousing occasionally to cry out with intense paroxysms of headache. Any attempt at examination is met by a fretful opposition and lack of attention which in the early stages are only too often thought to be due to sheer bad temper Mental slowness is more often met with in this than in any other intracranial disorder A question put to the patient may remain unanswered as if unheard for a minute or more and then just when it is about to be repeated a perfectly appropriate answer will be given in a petulant voice The patient may often be seen tentatively covering first one eye and then the other on account of double vision and in such cases an obvious internal strabismus may be present

The optic fundi in cases of cerebral abscess commonly show papillœdema if the condition lasts for more than a few weeks The swelling of the disks may come on with great rapidity and attain 3 to 4 dioptres of swelling with numerous hæmorrhages during the course of a few days It *not infrequently continues to increase in* severity for some days after the abscess has been drained and may even appear for the first time during this period Some degree of neck rigidity and a weakly positive Kernig s sign are not uncommonly met with particularly when the abscess is situated in the *cerebellum or when an appreciable degree of meningeal reaction is present* Local tenderness of the skull to firm pressure or percussion is a common finding and may afford valuable help in localising the abscess in doubtful cases The patient may rapidly become emaciated to a remarkable degree especially when the abscess is in *the cerebellum*

Localising signs will naturally vary with the position of the abscess Temporal abscess usually begins in the inferior portion of the lobe and extends upwards and forwards When situated on the left side in a right handed person one of the earliest *focal* disturbances to occur is disorder of speech At first this takes *the form of* difficulty then of inability to name objects correctly later difficulty in understanding spoken and written language and paraphasia make their appearance Naturally speech disturbances are not met with in right sided temporal lobe abscesses except in strongly left handed persons Another early sign of temporal abscess is disturbance of the contralateral fields of vision This nearly always takes the form of a congruous upper quadrantic hemianopia which gradually spreads to involve the lower quadrants until a complete hemianopia is present As the abscess extends forward towards the motor projection fibres weakness of the opposite side of the face of a supranuclear *type* develops to be followed by similar weakness of the contralateral arm and then of the leg until a complete hemiparesis may be present with characteristic increase in the tendon reflexes diminution or loss of the abdominal reflexes and an extensor plantar response Contralateral sensory disturbances may be met with but they are late to appear and by no means common Epileptic disturbances may occur in temporal lobe abscesses and when these are deeply situated the fits may assume a characteristically uncinate form

Abscesses in the frontal lobes are on the whole more silent than *those in the* temporal lobes Whether adjacent or metastatic in origin they usually originate well forward in the prefrontal areas and may attain a very large size without producing any localising signs whatever Mental change of the kind already mentioned may be an unduly conspicuous feature Apathy and forgetfulness may be marked and an early loss of sphincter control may be noted As the abscess extends backwards towards the motor area a contralateral hemiparesis develops involving face and arm before the leg and if the lesion is on the left side an increasing degree of executive aphasia may be in evidence in normal persons *Epileptic fits are not uncommon*

the past the recovery rate has been low but with modern neuro surgical technique a high proportion of recoveries can be obtained Unfortunately epileptic fits subsequently occur in approximately 50 per cent of cases recovering from cerebral abscess

(2) ENCEPHALITIS LETHARGICA (see p 1414)

(3) ENCEPHALITIS ASSOCIATED WITH ACUTE SPECIFIC FEVERS

Ætiology —Acute encephalitis may occur as a rare complication of a number of acute specific fevers especially of the exanthemata In some cases the brain alone may be involved but in others the nervous system may be more widely affected and *the picture is rather that of an encephalomyelitis* The fevers most commonly associated with this complication are measles and vaccinia but it occurs also with variola scarlatina mumps and varicella and many other acute febrile disorders The incidence of encephalic complications of these diseases varies noticeably from time to time

The exact relationship of the encephalitis to the preceding infection is by no means clear nor is it certain that the cerebral complications of the different exanthemata are identical The hypothesis that the exanthem merely serves to activate some unknown causative agent such as a latent virus is without confirmation It must also be borne in mind that all cerebral complications of acute fevers are not necessarily encephalitic but may result from vascular occlusion by thrombosis or embolism or from hæmorrhage or from meningitis

Pathology —In a great many cases recovery ensues and the pathology of the condition remains unknown A considerable number of cases of measles and vaccinial encephalitis have however been subjected to full pathological examination and have shown a fairly constant condition of the nervous system and the much rarer examples following other fevers have generally conformed to this picture The brain and spinal cord show diffuse congestion particularly of the white matter sometimes causing petechial hæmorrhages Numerous areas of acute demyelination occur particularly in the perivascular zones These are so constant as to have suggested the title perivascular myelinoclasis (Hurst) for this group of disorders In addition there is a marked perivascular infiltration with round cells and a more diffuse cellular reaction in the nervous tissue with mobilisation of microglia and proliferation of the astrocytes

Symptoms —The time of onset of encephalic symptoms is fairly constant in each exanthem In measles it is commonest towards the end of the first week in vaccinia from 10 to 14 days after the vaccination and in variola during the second week of the eruption Common symptoms are drowsiness increasing in severe cases to coma headache convulsions cranial nerve palsies dysarthria and dysphagia and in some cases myoclonic or choreiform movements Slight signs of meningeal irritation such as neck rigidity irritability and photophobia may occur and there may be an increase in the fever Papillœdema may develop In cases associated with myelitis marked weakness in the lower limbs with retention of urine is common Loss of the abdominal reflexes and extensor plantar responses are frequent The cerebrospinal fluid is commonly under increased pressure and shows an increase in protein content with a mild lymphocyte pleocytosis (10 to 50 per c mm) The Lange colloidal gold reaction may be strongly positive and sometimes paretic in character The content of sugar and chlorides is normal

Diagnosis —The occurrence of symptoms of this order at the significant period of the different diseases makes the diagnosis in most cases clear It should be remembered however that acute fevers in children may determine the moment of onset of tuberculous meningitis and that vascular disorders may occur in a similar setting

Prognosis —In cases which do not succumb to coma or convulsions during the first week recovery is the rule and is usually remarkably complete Residual paralyses

arise when a cerebral abscess is causing a brisk meningeal reaction and actual infection of the subarachnoid space is imminent In such cases the symptoms and signs of the two diseases are likely to be superimposed on one another The finding in such cases of a turbid fluid without visible organisms which is sterile on culture with normal salt and sugar content is very suggestive of an abscess with an acute meningeal reaction

2 *Localised meningitis* —This condition often affords the most difficult problem in the differential diagnosis of cerebral abscess In the presence of an acute infection on the outer aspect of the dura, especially if there is an extradural abscess as is so often the case in mastoid disease it is not surprising that there should be a brisk local inflammatory reaction of the leptomeninges on the inner aspect of the dura This local area of meningitis may produce the same local symptoms and signs as an abscess in the same locality and if it involves the base of the brain may also give rise to all the signs of raised intracranial pressure by obstructing the normal circulation of cerebrospinal fluid In otitic cases this is particularly likely to occur in the posterior fossa thus simulating a cerebellar abscess On the whole such cases come on more rapidly than abscesses and the symptoms and signs are more fluctuant The tempera ture is usually higher and the pulse rate more rapid than in abscess and the signs of meningeal irritation more marked The central nervous signs are those which might be expected to result from a lesion on the surface rather than in the substance of the brain for example cranial nerve palsies There seems every reason to suppose that in some cases this localised meningitis is capable of undergoing complete resolution especially since the introduction of antibiotics On the other hand it may be but the prelude of a general meningeal spread

3 *Infective venous sinus thrombosis* —This condition seldom resembles cerebral abscess sufficiently closely to present serious difficulty in diagnosis It is character ised by high, swinging fever with frequent rigors intense toxæmia and the other evidences of a pyæmic state There are no signs indicative of raised intracranial pressure or of local disturbance of brain function

4 *Otitic hydrocephalus* (see Hydrocephalus pp 1399 and 1404) —Otitic hydro cephalus is a condition almost confined to children and adolescents It is character ised by the symptoms and signs of raised intracranial pressure including papillœdema without signs of focal damage to the brain Its onset is more acute and the symptoms more violent than in cerebral abscess and the patient s general condition between paroxysms of headache remains remarkably good Apart from an increase in its pressure and quantity the cerebrospinal fluid is quite normal

Cerebral abscess may be distinguished from cerebral tumour by its association with suppurative conditions elsewhere in the body the rapid increase in symptoms the general reaction of the patient and the changes in the cerebrospinal fluid In spite of these criteria chronic cerebral abscesses are not infrequently operated upon in the belief that they are true neoplasms

Course and Prognosis —The natural termination of a cerebral abscess which is not drained is in the vast majority of cases the death of the patient Cases of spontaneous evacuation of the pus through the ear or nose are recorded in the litera ture and in a small number of cases the pus becomes inspissated and the capsule so enormously thick that the abscess may lie dormant in the brain for many years and become calcified Such abscesses may later be removed bodily as encapsuled ' tumours , the nature of which is only discovered after section Death takes place from the results of raised intracranial pressure from acute meningitis from spread of the infection to the general subarachnoid space or from rupture into the ventricle

Treatment —*The treatment of cerebral abscess is surgical* The condition is one of the greatest urgency as death may occur at any moment Surgical treatment should only be entrusted to an experienced neuro surgeon and direct drainage through the portal of entry *e g* the middle ear or frontal sinus carries a high mortality In

has been the first symptom and is the result of the symmetrical demyelination of the occipital white matter As the disease spreads forwards into the temporal regions bilateral deafness appears and later bilateral ataxy and astereognosis—due to parietal involvement bilateral spastic paralysis—the result of central involvement, and complete amentia—due to callosal and prefrontal involvement develop

In those cases in which the initial seat of the disease is in the temporal central or frontal regions the first symptom to appear is obviously determined by the location and the order of development of symptoms will be changed but the mode of progress is the same in all Where the disease starts on one side only hemianopia or hemiplegia is the first symptom and these are followed by the train of added signs produced by the extension of the disease into other regions Complete mindlessness and paralysis always dominate the clinical picture in the end The disease process within the brain sometimes causes swelling with increase of intracranial pressure and signs of the latter may appear in the form of headache, vomiting and papillœdema Such cases are not common and most of them have been regarded in life as cases of intracranial tumour Fits are by no means uncommon Sometimes they constitute the initial manifestation of the disease and they may occur at any time during its course and may be local or general Fever is usually absent but there may be irregular pyrexia and some of the more acute cases have been pyrexial throughout The cerebrospinal fluid is normal in the majority of the cases but sometimes there is an increased protein content and a small excess of lymphocytes

Diagnosis —The onset with cerebral blindness or with bilateral deafness followed by signs of progressive cerebral destruction is so rare in any other disorder as at once to suggest the diagnosis of Schilder s disease indeed no less than two thirds of the reported cases have shown this picture When the disease begins unilaterally and more particularly when headache vomiting and papillœdema are present the distinction from intracranial tumour is difficult or even impossible for in both diseases the local commencement and the progressive destruction occur In Schilder s disease however high grade papillœdema is not met with and consecutive optic atrophy does not occur It should be borne in mind that any locally commencing progressive destruction of the brain may be an example of this malady

Course and Prognosis —In most cases Schilder s disease is regularly progressive to a fatal termination In some however periods of standstill have been noted while in a few others marked improvement for a time has occurred The duration has varied from 7 days to 36 months with an average of 9 months

Treatment —No treatment is at present known that will influence the course of this disease

(5) SUBACUTE INCLUSION BODY ENCEPHALITIS

In recent years a type of subacute encephalitis at present only observed in children and adolescents has been reported by Dawson Van Bogaert Greenfield and others

Pathologically it is characterised by the presence of inclusion bodies in the nerve cells generally regarded as the hallmark of virus diseases together with polioclasis and neuronophagia

Together with this is a degree of demyelinisation and sclerosis of the white matter reminiscent of the leuco encephalitides of the Schilder type

Clinically the disorder runs a progressive subacute course towards a fatal termination The earliest symptom is usually mental deterioration often associated with epileptic manifestations Later involuntary movements of various kinds occur and the child gradually develops the picture of bilateral rigidity of extrapyramidal type with relatively few pyramidal signs until death occurs at a stage of profound dementia with akinesis and contractures

are exceptional In a small number of cases some residual intellectual impairment may result and in other cases a liability to fits The mortality in vaccinal cases is from 25 to 40 per cent , that in measles and the other common exanthemata very much lower

Treatment —This is symptomatic There is no evidence that specific antisera when available, affect the course of the nervous complications

(4) SCHILDER S DISEASE

Synonym —Encephalitis Periaxialis

Definition —A malady characterised anatomically by a progressive and massive demyelination of the white centres of the cerebral hemispheres, proceeding from a *single focus or from two symmetrical foci, and producing the clinical picture of* progressively increasing failure of cerebral function local at first but advancing in terms of the functions of the contiguous regions which are next affected, by the spread of the disease from its starting point

Ætiology —Nothing is known *of the essential nature of the disease,* nor is it certain that all cases included under this heading form a homogeneous group Origin ally regarded as an inflammatory probably an infective, disease the increasing evidence of its familial incidence suggests that it may be primarily degenerative It has also been suggested that those cases in which an inflammatory reaction is present may be infective and those in which it is absent—as it may be—degenerative Many of the reported cases have occurred in childhood even as early as the second year The latest case was in the fifth decade of life The sexes are equally affected

Pathology —The characteristic lesion consists of (1) A primary demyelination and later, destruction of the axis cylinders of the central white substances of the cerebral hemispheres which till very late spares the subcortical zone of white fibres and the radial cortical fibres and produces a translucent jelly like appearance of the oval centres (2) A very early and perhaps primary overgrowth of the neuroglia forming a *feltwork,* which is particularly intense round *the vessels (3) A general* infiltration of the white matter of the brain with round cells most of which are engaged in the removal of altered myelin or in the formation of neuroglial fibres

The process commences most commonly as symmetrical patches of demyelination in *either occipital white centre* less *frequently in both temporal white centres* or in both prefrontal white centres, and spreads directly thence until the whole of the oval white centres becomes demyelinated The corpus callosum is involved and the demyelination spreads downwards through the crura into the brain stem Sometimes especially in the central regions the disease starts on one side and after playing havoc with the white centre of one hemisphere spreads across the corpus callosum into the other The resulting picture of a brain normal on the surface and on section with apparently normal cortex and intact subcortical white bands but with the oval centre completely changed and translucent, is peculiar to this disease Not infre quently other patches *of the disease may be scattered throughout the central nervous* system. This scattered distribution and the prominence of demyelination bring Schilder s disease very close to disseminated sclerosis and it has actually been de scribed as disseminate sclerosis in childhood but the massiveness and mode of *spread of the lesions together* with their distribution with predilection for the brain and avoidance of the spinal cord its incidence in childhood and its entirely different symptomatology separate Schilder s disease sharply from di seminated sclerosis It is largely to Collier that we owe the clinical recognition of this malady

Symptoms —The clinical aspect is precisely that which might be expected from a progressive destruction of cerebral function spreading by contiguity from *the initial seat of the disease* In many of the cases blindness—by which is meant blind ness without any change in the optic disks and with pupils reacting normally to *light*—

in the seventh decade of life but it was rare in young children and seemed to be most incident in the first half of adult life The mode of infection is unknown According to von Economo when once the virus obtains access to the nervous system it spreads as in other cases of virus diseases of the nervous system by axonal routes Its effect remains confined to the nervous system but the occurrence of progressive nervous sequelæ long after the acute illness which is such a marked characteristic of the disease suggests that the virus may survive in the nervous system for long periods of time

The height of the epidemic incidence of lethargic encephalitis has many times coincided with a severe epidemic of influenza but no further connection between the two conditions is known Claimed at one time as an aberrant form of poliomyelitis infection von Economo s disease has proved quite distinct both in its age incidence seasonal prevalence morbid anatomy and symptomatology Economo first succeeded in transferring the disease to the monkey by intracerebral inoculation in 1916 Subsequent smaller epidemics in Japan and St Louis though conforming in general to the features of the pandemic of 1917–1920 have shown sufficiently constant variation in age incidence and death rate as well as clinical feature to make it seem likely that there exist more than one strain of the virus

Pathology—The pressure and quantity of the cerebrospinal fluid are always increased and in a few of the cases blood or the products of hæmorrhage are present In about one third of cases the cell count has been normal In the rest there has been a moderate lymphocytic pleocytosis with little or no protein increase the titre of the sugar tending to a high normal and that of the chlorides being normal No prognostic indications can be derived from the nature of the fluid The vessels of the brain are markedly congested and full of blood and the colour shows a characteristic change from the normal throughout the whole of the grey matter varying from a rosy flush to a deep salmon pink giving rise to the term the rose coloured brain When hardened in formalin this colour becomes a heavy purple grey Both subdural and deeply seated hæmorrhages are occasionally found Economo describes the anatomical picture as one of unvarying constancy It is that of an œdematous and congested brain with all the grey matter conspicuously reddened in contrast to the white matter which is of normal colour There is a non purulent and properly speaking a non hæmorrhagic inflammation of the whole grey matter exclusively, the white matter being uninvolved There is most conspicuous perivascular lymphocytic cuffing remarkable for the absence of any polymorphs with an intense cellular infiltration of the grey matter with elements of the microglia while the neuroglia is unaltered and demyelination does not occur Accompanying and succeeding these inflammatory changes is a certain measure of neuronophagia with primary loss of the ganglion cells

Symptoms—In the acute forms of the malady the onset is often ushered in by general symptoms such as shivering malaise headache and fever and bodily pains a thickly coated white tongue and constipation and sometimes vomiting and persistent hiccough This train of symptoms usually appears in the story as an attack of influenza The pyrexia does not usually last longer than a week Countless such attacks of influenza distinguishable only by the occurrence of transient diplopia or of slight somnolence and often even without any such distinguishing features have been completely recovered from at the time but have been followed after long intervals by the slow onset of the Parkinsonism of lethargic encephalitis Again the epoch of infection may apparently give rise to no symptoms at all and long afterwards an insidious onset of Parkinsonism ensues

The Nervous Signs—*Mental symptoms*—An increasing lethargy which often becomes very deep is present in many of the cases In this condition the patient will lie for days without stirring a muscle taking no heed of his surroundings and passing the dejecta under him unheeding Yet when roused by command and

VIRUS DISEASES OF THE NERVOUS SYSTEM

Certain viruses have a selective affinity for the nervous system and are therefore spoken of as neurotropic They act upon the nerve cell, and to a less degree upon glia cells, but not upon the white matter They are capable of multiplication and of exerting their pathogenic action only within the nerve cell where their life and activity are short lived

The essential lesion resulting from their presence is an acute necrosis of the nerve cell leading to the death and destruction or to the damage of the cell A secondary glial and vascular reaction ensues as a result of which lymphocytes pass into the cerebrospinal fluid from the perivascular spaces in the affected regions of the nervous system

The so called post infective encephalitis that may follow the acute exanthemata has not the pathological characters common to the proved virus infections of the nervous system since the lesion is one of demyelination and not an attack upon the nerve cell The nature of this form of encephalitis remains obscure (see p 1411)

ENCEPHALITIS LETHARGICA

Synonym —Epidemic Encephalitis

Definition —An acute febrile disease occurring sporadically and epidemically due to the infection of the nervous system by a virus which has not yet been identified but which can be inoculated into the nervous system of monkeys reproducing the disease The malady has its principal incidence upon the upper parts of the nervous system the cerebrum basal ganglia and brain stem Though very definite it is remarkably polymorphic, and it is sometimes mono symptomatic, and its type has changed greatly during the passage of an epidemic The absence of evidence of case to case infection has necessitated the assumption that infection is transferred by carriers or by those in the pre symptomatic stage of infection only

History —When we read of the influenza epidemic which swept over Europe in 1580 and which was accompanied by a malady so peculiar as to gain the title of ' schlafkrankheit , and afterwards of the epidemic described by Sydenham in 1675 as febris comatosa the sleeping sickness of Tubingen in 1712 and Dubini s epidemic of the fatal electrical chorea in Northern Italy in 1846 we cannot but agree with von Economo s conclusion that these epidemics were epidemics of lethargic encephalitis The subsequent epidemics of Mauthner s Nona in Piedmont in 1891 and also Pfuhl Leichtenstern s hæmorrhagic encephalitis in 1905 have been shown to be similar to lethargic encephalitis both clinically and pathologically The malady last became pandemic in Britain and Northern Europe from 1917, reaching a maximum in 1920 and then declined almost to vanishing point over the next 15 years

In this country sporadic cases of sufficiently definite characteristics to stand up to both clinical and pathological criteria of diagnosis have continued to make their appearance but they are rare *It should be remembered that many cases thought* to be of this nature prove at autopsy to be due to tumours or other causes On the other hand the continued appearance of cases of Parkinsonism in young people not infrequently associated with other post encephalitic sequelæ makes it seem likely that instances of the infection so mild as not to produce clinically recognisable symptoms are not infrequent

Ætiology —During the period of its frequent incidence the disease occurred both sporadically and epidemically with no centre of spread It was more prevalent in the cold season of the year No age was exempt from the malady and cases occurred

stiff the arms held away from the trunk the whole appearance of the patient closely resembling that of paralysis agitans Rapid fluttering of the eyelids when gently closed is characteristic of this condition The spontaneous involuntary movements may be of a rhythmic tremulous nature as in paralysis agitans or there may be slow rhythmic choreiform athetoid myoclonic irregular or highly complicated movements these may be met with at any stage of the malady but most commonly appear some little time after the acute stage has passed away Fibrillation and fascicular twitching of the muscles is very common in the acute stage In cases where bulbar symptoms either of a spastic or flaccid kind are present hypersalivation of the nature of a true sialorrhœa is often a most troublesome symptom

In addition to the above common symptoms and signs other indications of involvement of the cerebral hemispheres may occur Bilateral spasticity with signs of involvement of the pyramidal systems increased jerks lost abdominal reflexes and extensor plantar responses are common Hemiplegia aphasia and hemianopia may occur Meningeal symptoms may be very marked in the early stages such as suboccipital headache painful stiffness of the neck head retraction vomiting and Kernig s sign Indeed rapidly fatal cases have occurred in which the clinical picture throughout was hardly distinguishable from that of acute meningitis but without any leucocytosis in the cerebrospinal fluid A major incidence of the lesions upon the cerebellum gives rise to the picture of acute cerebellar ataxy following a lethargic onset, and the end result may be a condition closely resembling a usual type of disseminate sclerosis Such cases make a good recovery in the course of time

Peripheral pains are sometimes very severe and are usually quite local They may be the first signs of the illness and may persist for months after recovery They are presumably due to the lesions around the nerve roots which have been already referred to

Spinal symptoms —Since lesions have been found in the spinal cord it is only to be expected that focal spinal symptoms should be met with in rare cases These are usually acute atrophic paralyses similar to those of poliomyelitis and recover completely It has been argued however that this atrophic palsy is due to a lesion of the spinal roots More severe lesions may apparently give rise to a condition resembling acute transverse myelitis

The incontinence which is almost constantly present even when the lethargy is far from deep is the result of the lethargy Transient conscious dysuria is however not infrequent in the early stages of the disease The deep reflexes may be lost in severe cases during the acute stages and they are usually absent in premortal conditions Otherwise they tend to be exaggerated especially if involvement of the pyramidal system be present The condition of the abdominal and plantar reflexes depends upon the presence or absence of lesions affecting the pyramidal tracts In the former case the abdominal reflexes will be absent and the plantar reflexes of the extensor type

Attention must be drawn to a group of cases in which the initial manifestations of the disease are so slight as not even to interfere with the daily work or to call for medical attention and yet in the course of months or it may be even years the most serious and completely incapacitating paralysis appears Such a patient may notice that he sees double and does not feel very well for a few weeks He recovers but after a few years begins to manifest the signs of a slowly oncoming Parkinsonism A similar result in the slow and late development of grievous symptoms may follow any attack of lethargic encephalitis and make the prognosis in this malady very difficult.

Sequelæ —The disabilities which this malady may leave in its wake are numerous and varied The mental paralytic and Parkinsonian end results have already been referred to but special mention must be made of the so called oculogyric crises and of involuntary spontaneous movements having the general features of habit spasms or tics

vigorous bodily stirring he will wake up and hold a very intelligent conversation, lapsing back at once when he is left alone even though his mouth be half full of unswallowed food In this condition flexibilitas cerea may often be demonstrated in the limbs The lethargy may last for 3 weeks or longer even in patients who completely recover It passes away gradually Unrousable coma is invariably a sign of impending dissolution Subsequent memory of events during the early days of the lethargy may be remarkably retained Insomnia may be a troublesome early symptom, and even when the patients are markedly lethargic they will complain that they cannot sleep *Occasionally reversal of sleep rhythm may occur, the patient sleeping soundly* all day only to become restless and overactive at night Lethargy however may be completely absent and the early mental state be that of vivacious excitement and talkativeness Irritability and restlessness may be present In some cases the first nervous sign may be delirium or mental aberration, which may rapidly develop into acute and violent mania such cases are rapidly fatal In cases which recover after severe symptoms considerable mental reduction and self obvious mental change may persist Indeed it has been said that no sufferer from this disease ever regains his original mentality, and it is a common experience to find the personality very seriously changed in the way of mental reduction Complete incapacity for any sustained work entire change of character anti social tendencies moral perversion and depressed neurasthenic states are not uncommon sequels of the disease, particularly when it occurs in children or adolescents (see also p 1634)

Convulsions are very rare but they may undoubtedly occur as in other forms of encephalitis Indeed the initial clinical picture may be dominated by convulsion and closely resemble status epilepticus from other causes

Ophthalmoplegia and other paralyses in the region of the cranial nerves are most often nuclear in type but peripheral paralysis of any cranial nerve may be met with most commonly unilateral paralysis of the facial nerve The pupils may show every abnormality which a lesion of the nervous system can produce Inequality unroundness eccentricity and loss of light reflex and ciliary paralysis may occur The loss *of light reflex may be unilateral The external ophthalmoplegia* being nuclear in origin, involves both eyes in terms of their conjugate movements and the upward and downward movements are as a rule more severely impaired than are the lateral movements '*Bilateral* ptosis is very usual and is a most important and valuable early indication of the disease' The common error is to consider it part of the sleepy state The nuclear ophthalmoplegia is often irregular giving rise to strabismus and diplopia Either in addition to the above or existing alone there may be peripheral paralysis of any of the oculo motor nerve trunks The degree of the ophthalmoplegia varies in different cases from slight diplopia with hardly noticeable strabismus to complete paralysis of both eyes It may be rapidly transient or permanently severe In severe cases which survive there is always some improvement in the degree of paralysis in the course of time

Vision—The diplopia and loss of accommodation cause much defect of vision but *many of the patients complain of a loss of vision in each eye* which is too great for any such explanation the cause of which is not yet explicable Papillœdema has been reported in a few cases It is transient and never reaches a high degree

Bilateral nuclear facial paralysis and bulbar paralysis are not uncommon Paralysis of any individual cranial nerve may occur, and also of any individual spinal root Such paralyses always completely recover in the course of time

Symptoms indicative of lesion of the basal ganglia are among the most common features of the disease and they are often the most persistent These consist of weakness of movement rigidity with slowness of movement and spontaneous involuntary movements The weakness rigidity and slowness of *movement give* rise to a peculiar immobility of facial and bodily expression and movement The face is mask like the neck stiff and the head moves little and slowly the trunk bent forward and

favour of survival The prognosis however as to how much permanent damage to the nervous system will eventually remain is hardly possible since slow improvement may go on for months and even years Of the acute cases occurring at the height of an epidemic, 40 per cent are quickly fatal 30 per cent are reduced to chronic invalidism and 30 per cent appear to recover completely (Economo) In most of these latter the syndrome of Parkinsonism subsequently appears after an interval which may be a few months or many years and the weakness rigidity and tremors which form this paralysis agitans like picture persist indefinitely

Treatment—Nothing being known of the infectivity and mode of spread of the disease isolation and disinfection are not usually employed Each case must in England be immediately notified to the public health authorities No treatment is known which has any specific influence upon the disease Intravenous injection of collosol iodine solution (150 ml for a dose) repeated on the second and fourth days has been advocated and is certainly without harmful effects but there is little evidence that it is of value There has as yet been little opportunity to investigate the effects of antibiotics It remains therefore to use those measures which will help to keep the patient alive and those which relieve symptoms Nasal feeding may be necessary Relief of the constipation is most important and is often followed by striking improvement in the symptoms After the acute stage treatment is concerned with combating the physical and mental listlessness and depression which so often persist and with the restoration of normal mobility and function to the limb In these physical and occupational therapy can play a useful part

HERPES ZOSTER

Synonym—Zoster Shingles

Definition—An acute infection of the posterior root ganglion by a neurotropic virus leading to severe pain in the distribution of the corresponding posterior root and to the appearance of a crop of vesicles in the cutaneous distribution of the root

Ætiology—The virus of zoster stands in some as yet undetermined relation to that of chicken pox and the appearance of the latter malady in a susceptible subject some 14 days after contact with a case of zoster has been too frequently recorded to be of the nature of coincidence

The disease is seen at all ages but according to Head is perhaps most common in adolescents In elderly patients it is frequently a more serious as well as a more painful affection than in young persons It may arise without discoverable cause and with a febrile reaction and considerable malaise It may also occur apparently symptomatically during the course of arsenical medication or during such illnesses as pneumonia tabes dorsalis and tuberculosis

Pathology—The essential lesion is an acute inflammation of the dorsal root *ganglion of the same histological character as the lesion of acute anterior poliomyelitis* There are degenerative nerve cell changes with accompanying microglial reaction and perivascular infiltration with round cells Later degenerative changes occur in the fibres of the dorsal roots and of the peripheral sensory nerves The Gasserian ganglion and the thoracic and upper two or three lumbar ganglia are most often affected There is an increased protein and lymphocyte count in the cerebrospinal fluid

Symptoms—There may be an onset with fever which persists for 2 3 or even 4 days There is from the first pain at the place at which later the herpetic eruption is to appear This occurs on the third or fourth day of the illness At first the rash is a patchy erythema upon which appear small vesicles filled with clear fluid From the fifth to the tenth day the vesicles dry up and shrink progressively until a scab is formed This finally drops off sometimes leaving considerable scarring These

Oculogyric crises —This term is applied to recurring attacks of tonic conjugate deviation of the eyes This is almost always upwards and is accompanied by wrinkling of the forehead extension of the neck and in fact all the muscular activity associated with the act of looking upwards Deviation of the eyes to one side is exceedingly rare The attacks may occur several times a day or only at an interval of months They are often very specific in their times of occurrence and may be precipitated by a variety of stimuli such as emotion fatigue or watching a moving picture The attack may last from a few minutes to many hours and often passes off only after sleep It is commonly associated with an intense degree of mental depression and while it lasts the patient may experience recurring obsessional thoughts be impelled to carry out stereotyped movements or develop ideas of reference, particularly feelings of *persecution*

Patients suffering from oculogyric crises always show some signs of Parkinsonism. The attacks often gradually grow less frequent over a period of years and may cease completely Their frequency and duration is in many cases considerably reduced by the regular administration of amphetamine sulphate 5 to 10 mg twice daily

Post encephalitic tics —A great variety of stereotyped involuntary movements are met with in post encephalitic subjects usually in association with some degree of Parkinsonism Rhythmic movements of the jaws tongue and face are common. Alterations in respiratory rhythm with sighing gasping inspirations may occur Torticollis indistinguishable from the variety met with in elderly subjects is not rare and there may be hideous recurring contortions of the face and trunk and most grotesque mannerisms of gait and speech

Diagnosis —A diagnosis of lethargic encephalitis is not infrequently made but must be received with the very greatest reserve at the present time Under this title *most neurologists have encountered a great variety of nervous disease including intra* cranial tumour, cerebral abscess, subdural hæmatoma tuberculous meningitis and the like In typical cases the diagnosis presents no difficulty, the rousable lethargy incontinence ophthalmoplegia and negative lymphocytic or blood containing cerebro spinal fluid being so characteristic as to preclude possibility of error The less usual forms of the malady and especially those with very gradual onset and slight symptoms often present great difficulty and require much care and full knowledge of the possible symptomatology of the disease for their recognition There is no specific laboratory test for the malady and the diagnosis must be based upon clinical grounds Where meningeal symptoms are prominent distinction has to be made from other forms of meningitis and from poliomyelitis Here the cerebrospinal fluid is of the highest importance as polymorphonuclear leucocytes occur very rarely in lethargic encephal itis In cases commencing with peripheral pains excitement maniacal symptoms or convulsions careful lookout should be kept for the advent of ptosis ophthalmoplegia or lethargy the appearance of which following such symptoms should at once suggest the diagnosis It must be borne in mind that the clinical picture of the disease may be dominated by a hemiplegic condition, and that an apoplexy may occur during the acute stage of the disease Slight cases of the disease are frequently unrecognised or are indeed unrecognisable in the early stages but here the diagnosis can often be *made with certainty from the end results the peculiar ophthalmoplegia* the spon taneous involuntary movements and the paralysis agitans like syndrome being almost pathognomonic of the malady

Course —The course of the disease is extremely variable It may be a slight transient illness lasting but a few days and leaving no sequelæ after a few weeks or a most malignant disease *fatal in a few days In others symptoms* indicative of fresh lesions may occur repeatedly weeks and even months after the onset

Prognosis —A rapid onset and quick development of severe symptoms marked pyrexia delirium and maniacal excitement are bad prognostic signs and indicate a rapidly fatal issue After the third week of the disease the probabilities are all in

Ætiology —The disease is generally transmitted either by the licking of a freshly abraded surface of skin or the bite of an infected dog In Eastern Europe and the Orient wolves not uncommonly transmit the disease and owing to extensive laceration of the tissues a greater proportion of people bitten by them develop the disease than with either dogs or jackals It has been estimated that wolf bites entail a mortality of 80 per cent In Trinidad in 1925 an epidemic of paralytic rabies in man was attributed to the bites of vampire bats cattle being the original source of infection

The virus of rabies —This belongs to the class of neurotropic viruses that have a special affinity for attacking the grey matter of the nervous system

Pasteur in 1881 discovered that rabies could be transferred in series from animal to animal by subdural inoculation of emulsions of central nervous tissue derived from an infected dog In rabbits after some twenty passages the virus became modified firstly the incubation period of ordinary street virus which varied from 8 to 60 days was reduced to 7 days and secondly it lost its capacity to reproduce the disease on subcutaneous inoculation Such a virus is known as fixed virus or virus fixé Street virus on the other hand is transmitted from the local wound via the peripheral nerves to the central nervous system and if the sciatic nerve be inoculated the lumbar cord becomes infectious several days before the virus can be demonstrated in the brain (di Vestea and Zagari) This accounts for the fact that cases bitten about the face head and neck have such a short incubation period The virus is destroyed at 50° C and is attenuated by drying—a fact made use of in the preparation of antirabic vaccine by the Pasteur method

Pathology —Excess of cerebrospinal fluid petechial hæmorrhages of the pia arachnoid and injection of its vessels may be found at autopsy Histological examination reveals cellular infiltration of the perivascular lymph spaces as well as Negri bodies within the cytoplasm of the nerve cells and their processes These bodies were described by Negri in 1903 They are globular or ovoid structures of variable diameter (0 5 to 25 0 microns) and are especially common in the Purkinje cells of the cerebellum and the hippocampus These inclusion bodies are present in the brain of 97 per cent of dogs infected with street virus

Symptoms —The period intervening between the bite and the clinical manifestations varies from 1 to 2 months as a rule the limits being 11 days to over a year Face head and neck bites have a shorter incubation period than those on the upper extremity and arm bites a shorter incubation than those implicating the leg The onset is generally sudden but prodromal symptoms are sometimes noted for a day or two before a hydrophobic syndrome appears For convenience three stages are described

1 *The invasion stage* —This includes prodromal features such as pain in the scar fever headache rapid pulse anxiety restlessness insomnia irregular and sighing respirations and phases of rushed speaking

2 *The stage of excitation* —This supervenes in 24 to 48 hours There is intense restlessness mental excitement hyperæsthesia and hydrophobia which consists of a sudden spasmodic spasm of the muscles of the mouth pharynx and larynx and to a greater or lesser degree the whole respiratory musculature A typical attack may be induced by offering the patient water As the glass approaches the mouth the head retracts in a series of spasmodic jerks associated with gasping respirations while any water reaching the mouth is immediately ejected The shoulders are elevated the chest expanded and the sterno mastoid and platysma muscles contracted Later the synaptic resistance in the reflex arcs become so lowered that a variety of sensory stimuli such as a sudden sound cold air strong light a strange smell and even the suggestion of water may suffice to induce the attack The voice is altered Frothy saliva collects in the throat and mouth and is flung off the lips during the attacks which may be characterised by intense fury or the most profound terror Lastly opisthotonus and general respiratory spasm are superadded In the interval the mind

scars may be anæsthetic to touch pinprick and temperature sense The pain before and during the evolution of the cutaneous lesion may be intense It is of a burning and itching quality, and in frail and elderly persons it may persist as a most intractable post herpetic neuralgia for months or even years

Herpes of the ophthalmic division of the fifth nerve is most commonly found in elderly persons Corneal vesicles may form and burst giving rise to ulcers which may spread and end in residual scarring (nebulæ) which impairs vision

Herpes of the geniculate ganglion occasionally occurs The vesicles are found in the pinna and there is pain in this region over the mastoid, and sometimes in the fauces (see pp 1248 1346)

Localised paralysis may accompany herpes Thus in ophthalmic herpes there is occasionally third nerve palsy, with ptosis and squint In geniculate herpes facial palsy with loss of taste over the anterior two thirds of the tongue is the rule In *herpes of the lower thoracic ganglia there may be paralysis of the oblique abdominal* muscles on the affected side The marked local bulging of the abdominal wall which ensues resembles at first sight the presence of an abdominal tumour These paralyses do not invariably clear up though the facial palsy of geniculate herpes does so more frequently than the paralysis of the abdominal muscles

Treatment —The course of the cutaneous lesions is not influenced by treatment which is directed to keeping the vesicles dry and free from infection For this purpose a dusting powder of starch or zinc oxide, or a collodion dressing may be used

During the acute stage pain may be relieved by aspirin or phenacetin but the post herpetic neuralgia so often met with in elderly patients may prove intractable and so severe as to render life scarcely tolerable It consists of a persistent burning soreness often associated with numbness and dysæsthesia over the area previously effected by the eruption

This pain is aggravated by fatigue worry and physical debility and often induces a neurotic reaction on the part of the patient or a state of depression in which suicide may be contemplated

Both analgesics and hypnotics are commonly needed over a period of many months The former may profitably take the form of some such mixture as the following tinct gelsemi min 10 phenazone gr 10 phenobarb sod gr ¼ Aq chlorof ad fl oz 1 t d s For the latter one of the short acting barbiturates is to be preferred A word of caution should be given against the dangers of excessive sedation in elderly subjects especially with bromides as a toxic confusional state is easily produced

A great variety of local applications have been used without avail Surgical measures such as division of peripheral nerves posterior spinal roots or the spino thalamic tract in the cord are equally ineffective As a last resort in the elderly depressed subject frontal leucotomy may be justified and while it does not remove the unpleasant sensation it allays tension and depression and frees the patient's mind from perpetual preoccupation with the pain which is one of the most noticeable features of this distressing malady

RABIES

Synonyms —Hydrophobia Lyssa

Definition —This is an infective disease due to a filtrable virus which is located in the salivary glands and central nervous system It is transmitted to man and most warm blooded animals through infective saliva of canines or blood lapping bats There is a long and variable incubation period and a short pyrexial illness of sudden onset characterised by fever nervous exaltation and violent muscular spasms involving the œsophagus and respiratory system *Once symptoms have supervened* the patient invariably succumbs

rabies prophylactic inoculation need not be advised unless fresh skin abrasions were present at the time.

Local treatment—If seen within 30 minutes bleeding should be encouraged by the application of a ligature just tight enough to obstruct the venous return and the parts bathed with permanganate solution Subsequently each tooth mark should be probed separately and cauterised or treated with pure phenol For 3 days the wound should not be sutured this particularly applies in the case of face bites

Antirabic vaccination—Owing to the long incubation period it is feasible to attempt immunising the patient either by the inoculation of attenuated living fixed virus, as in the Pasteur and Hogyes methods or by the injection of carbolised or etherised vaccines in which the fixed virus has been killed The Pasteur treatment consists of a series of 18 injections of emulsions made from the spinal cord of rabbits which had been dried for periods of from 14 to 3 days Semple introduced carbolised vaccine the most potent preparation consists of a 5 per cent carbolised suspension of sheep brain infected with Paris virus In mild cases the course consists of 2 ml. injected subcutaneously each day for 7 days in average cases of 5 ml for 14 days and in severe cases such as head neck and face bites in wolf bites, or in children bitten on the bare skin 10 ml are injected daily for 14 days Itchy swellings may appear at the site of the inoculations about the eleventh day but other complications following inoculation are fortunately rare. Paralytic accidents however have been recorded with all methods they include a mild facial neuritis dorso-lumbar myelitis and an ascending paralysis of Landry s type which is fatal in about 30 per cent of cases

Treatment of the paroxysm—No specific treatment is known Measures directed to alleviate the suffering of the patient should be instituted These include chloroform inhalations and morphine hyoscine chloral and atropine in large doses Curare has been employed for the relief of spasms

ACUTE ANTERIOR POLIOMYELITIS

Synonyms—Infantile Paralysis Heine Medin Disease

Definition—An acute infectious disease characterised in its fully developed form by local or widespread muscular paralysis consequent upon the destruction by the action of a specific neurotropic virus of anterior horn cells in the spinal cord or corresponding cells in the medulla

Ætiology—The disease occurs in both sporadic and epidemic manner and has its greatest incidence in countries in the temperate zones The most severe epidemics have occurred in the countries of northern Europe and North America but in the last 25 years it has appeared with increasing frequency in Australia New Zealand and South Africa and such island communities as Malta and Mauritius have not been spared During the War of 1939–1945 a particularly virulent form was prevalent in North Africa and the whole Mediterranean littoral

It shows a marked seasonal variation being commonest in the hotter months of the year In northern Europe the incidence usually begins to increase towards epidemic proportions in July and slackens off in October or November Sporadic cases however occur throughout the year

A conspicuous feature of the disease is its preference for the young although no age is immune In the early years of this century its maximal incidence among infants led to its being named infantile paralysis and at that time the greatest number of cases occurred in the second and third years of life Before the age of 1 year the infant appears to be immune

Over a period of 50 years there has been a steady tendency for the disease to attack older age groups and at present the maximal incidence is between the ages

is clear the patient remaining quietly at rest in bed Examination of the central nervous system reveals as a rule, nothing more than increased deep reflexes Glycosuria is not uncommon and vomiting exhaustion and emaciation characterise the final stage of the illness Death during the paroxysm may occur from dilatation of the right heart though sometimes near the end the spasms ameliorate or cease altogether

3 *Stage of paralysis* —If the patient survives long enough paralysis of various types including ascending spinal paralysis paraplegia and hemiplegia may supervene The patient lies helpless and exhausted and generally dies in coma In man this stage is rarely seen in canine transmitted rabies but paralytic rabies is commonly encountered in the bat transmitted variety in Trinidad

In the Trinidad outbreak all the cases were of this variety and all proved fatal The onset is acute with fever and headache Numbness and burning sensations in one or both legs paresis of the legs and retention of urine follow After 2 or 3 days the paraplegia becomes more complete and the plantar and tendon reflexes disappear One limb is commonly affected before the other In a few days the paralysis begins to ascend involving the muscles of respiration articulation and deglutition There is dyspnœa and restlessness The sufferer remains conscious but may be delirious Sensory changes are of variable intensity A final brief coma precedes the fatal issue During this time the temperature swings round 103° F and there is profuse sweating Hydrophobic symptoms are exceptional, and when present slight The cerebrospinal fluid yields an increased globulin content but is otherwise normal The duration of the illness is from 4 to 8 days

Rabies in the dog —These animals never show the hydrophobic syndrome observed in man The earliest manifestation appears to be a change in temperament followed by irritation and exacerbations of vicious fury in which the animal runs amok biting wildly anything in its path Later swallowing becomes difficult the bark is altered the jaw drops and general paralysis ensues Death invariably follows some 2 to 5 days after the first symptoms appear In dumb rabies the stage of excitation is absent.

Diagnosis —As a rule little difficulty is experienced in diagnosis but occasionally tetanus the cerebral type of typhus fever, bulbar paralysis from any cause and datura and other poisonings encountered in Oriental countries may need differentiation Lyssophobia or hysteroid counterfeiting of the disease generally manifests itself within the first 10 days and is unaccompanied by fever or other serious features

Prognosis —By no means all patients bitten by rabid animals die but once clinical manifestations appear the disease invariably ends fatally Estimates varying from 5 to 33 per cent have been made of the death rate in untreated patients but of those receiving early anti rabic inoculations in Pasteur institutes not more than 1 per cent die The mortality varies with the site of the bite the interposition of clothing the number of tooth marks the extent of tissue laceration and the rapidity with which efficient local treatment has been instituted Head face and neck bites are particularly dangerous as well as bites from wolves and jackals

Treatment —This is entirely preventive and in England the muzzling order and the strict quarantine of all imported dogs has led to the eradication of rabies In endemic areas canine bites should be promptly treated and the suspected dog chained up muzzled and kept under observation Should the animal be alive at the end of 10 days it is proof that the bitten person has not been infected This rule universally followed in Pasteur institutes is based (1) on the knowledge that the infected dog never survives longer than 6 days from the onset of its illness, and (2) that the saliva of a rabid dog is never infective for more than 4 days before the onset of symptoms In suspicious cases especially the head face and neck bites treatment should be commenced without delay and discontinued if the dog survives

The virus of rabies differs from that of yellow fever in not passing through the intact skin and where there is a history of being licked by an animal suspected of

rabies prophylactic inoculation need not be advised unless fresh skin abrasions were present at the time

Local treatment —If seen within 30 minutes bleeding should be encouraged by the application of a ligature just tight enough to obstruct the venous return and the parts bathed with permanganate solution Subsequently, each tooth mark should be probed separately and cauterised or treated with pure phenol For 3 days the wound should not be sutured this particularly applies in the case of face bites

Antirabic vaccination —Owing to the long incubation period it is feasible to attempt immunising the patient either by the inoculation of attenuated living fixed virus as in the Pasteur and Hogyes methods or by the injection of carbolised or etherised vaccines in which the fixed virus has been killed The Pasteur treatment consists of a series of 18 injections of emulsions made from the spinal cord of rabbits which had been dried for periods of from 14 to 3 days Semple introduced carbolised vaccine the most potent preparation consists of a 5 per cent carbolised suspension of sheep brain infected with Paris virus In mild cases the course consists of 2 ml injected subcutaneously each day for 7 days in average cases of 5 ml for 14 days, and in severe cases such as head neck and face bites in wolf bites or in children bitten on the bare skin 10 ml are injected daily for 14 days Itchy swellings may appear at the site of the inoculations about the eleventh day but other complications following inoculation are fortunately rare Paralytic accidents however have been recorded with all methods they include a mild facial neuritis dorso lumbar myelitis and an ascending paralysis of Landry s type which is fatal in about 30 per cent of cases

Treatment of the paroxysm —No specific treatment is known Measures directed to alleviate the suffering of the patient should be instituted These include chloro form inhalations and morphine hyoscine chloral and atropine in large doses Curare has been employed for the relief of spasms

ACUTE ANTERIOR POLIOMYELITIS

Synonyms —Infantile Paralysis Heine Medin Disease

Definition —An acute infectious disease characterised in its fully developed form by local or widespread muscular paralysis consequent upon the destruction by the action of a specific neurotropic virus of anterior horn cells in the spinal cord or corresponding cells in the medulla

Ætiology —The disease occurs in both sporadic and epidemic manner and has its greatest incidence in countries in the temperate zones The most severe epidemics have occurred in the countries of northern Europe and North America but in the last 25 years it has appeared with increasing frequency in Australia New Zealand and South Africa and such island communities as Malta and Mauritius have not been spared During the War of 1939-1945 a particularly virulent form was prevalent in North Africa and the whole Mediterranean littoral

It shows a marked seasonal variation being commonest in the hotter months of the year In northern Europe the incidence usually begins to increase towards epidemic proportions in July and slackens off in October or November Sporadic cases however occur throughout the year

A conspicuous feature of the disease is its preference for the young although no age is immune In the early years of this century its maximal incidence among infants led to its being named infantile paralysis and at that time the greatest number of cases occurred in the second and third years of life Before the age of 1 year the infant appears to be immune

Over a period of 50 years there has been a steady tendency for the disease to attack older age groups and at present the maximal incidence is between the ages

of 5 and 10 This curious change in age distribution taken with the unfortunate fact that the incidence of paralytic poliomyelitis seems to increase rather than to decrease with the improved standards of hygiene in more advanced communities suggests that whereas in primitive communities children come frequently in contact with the virus in early life and so acquire immunity, those in more advanced communities escape this early inoculation, some of them only to fall victims to a virulent attack in later childhood

The successful transmission of the disease from man to monkeys by Landsteiner and Popper in 1909 and the subsequent researches of Flexner and Lewis and others as to the nature of the infecting agent proved to be landmarks in the development of our knowledge of virus diseases in general and of those of the nervous system in particular

It is now known that the causative agent of the disease is a virus which is amongst the smallest so far identified It is distributed widely in the human race and is commonly a harmless inhabitant of the naso pharynx and intestinal canal By modern methods it can be recovered from the naso pharyngeal washings and the fæces of both clinical cases and many contacts as well as from flies and communal sewage in affected areas It is now recognised that only a minority of the individuals harbouring the virus develop even mild symptoms of disease and that of these not more than a fifth develop paralysis There is thus a large pool of unaffected " carriers in any community that is affected and these probably play a major rôle in transmission of the disease This is in accordance with the known fact that 50 to 80 per cent of town dwellers in countries much affected by the disease have protective antibodies in their sera at a high titre Three distinct types of the virus have now been identified Type I (Brunhilda) which is at present the most virulent and carries the highest incidence of paralysis Type II (Lansing) which can be adapted to be pathogenic to rodents and Type III (Leon) All three types have been responsible for paralytic attacks in the human They are serologically distinct but it is at present by no means clear to what extent infection with one type confers protection against the natural disease caused by the other types The rare occurrence of second attacks of the disease strongly confirms that cross immunity is incomplete

A clinically recognisable attack of poliomyelitis whether paralytic or not leads to the development of specific antibodies in the blood which with the rare exceptions mentioned above confer lifelong immunity from a further attack Such antibodies are not present in the sera of individuals from isolated and unaffected communities or in those of susceptible individuals in affected communities On the other hand the high incidence of natural immunity among adults especially the town dwellers in affected populations confirms the belief that one or more subclinical attacks occur during many such persons lifetimes The immune body is carried by the gamma globulin fraction of the plasma and is at present the subject of intensive research in the hope of finding a satisfactory method of immunisation against the disease

The method of spread of the infection has been a matter of controversy for many years It has been generally accepted that unaffected carriers play a larger part in the process than do recognisable cases of the disease Although the participation of flies in the spread of the disease cannot be excluded it is clear that the principal agency concerned is human contact The main matter of dispute has been whether the infection is carried by droplet spread from the naso pharynx and upper respiratory tract or by the various methods of fæcal contamination from the gastro intestinal canal The evidence for droplet spread is strong and epidemiological studies have shown a close association between cases of the disease and human movement in circumstances in which spread by the excreta was unlikely The undoubted association between tonsillectomy and the development of bulbar poliomyelitis also indicates the naso-pharynx as a potential source of infection On the other hand the major incidence of the disease in hot weather has always suggested that it was spread by

fæcal contamination and there is now convincing evidence that the gastro intestinal tract acts as a portal of entry for the virus and that in most epidemics it is the principal one The virus can be recovered from the stools of patients for several weeks after an attack as well as from those of intimate contacts and from communal sewage The method of transmission is largely by human contact operating through such agencies as contaminated food eating utensils and latrines It is possible that milk and water may also play a part Although the virus can be recovered from flies in infected areas the part they play as vectors has not yet been determined It used to be said that case to case infection did not occur, but this statement will no longer bear critical examination However such occurrences are extremely rare in institutions where cases are treated with careful barrier nursing precautions

There is still considerable uncertainty as to how the virus when it reaches a susceptible host in adequate dosage breaches the defences of the body surface and reaches the nervous system There is evidence that in so doing it is aided by a lowering of the victim s general resistance or by local trauma such as tonsillectomy or by local disturbance such as may cause the diarrhœa which often precedes attacks in which a gastro intestinal origin of the infection is to be suspected Since the work of Hurst and Fairbrother later confirmed by Howe and Bodian it is evident that the virus having penetrated the body s defences reaches the nervous system by axonal pathways The original view that the olfactory nerves were the agents of transmission has been abandoned and it is now thought that the nerve fibres of the gastro intestinal canal and of the tonsils are responsible The virus is capable of transmission along axones but can only proliferate in the bodies of nerve cells Examination of the nervous systems of humans or of experimental animals dying of the disease shows that the virus is widely distributed in the brain and spinal cord but reaches its highest concentration in the anterior horn cells of the spinal cord especially of the lumbar enlargement the motor nuclei of the brain stem and motor cells of the cerebral cortex Another subject of controversy has been whether the entire sequence of events observed in acute poliomyelitis can be explained in terms of a process confined to the nerve cells or whether there is an associated systemic infection The high proportion of cases in which no paralysis occurs the associated blood changes and the widespread occurrence of immune bodies in the blood stream are points suggestive that a systemic invasion does take place although the virus has only rarely been recovered from the blood in human cases and the visible pathological changes seen after death are confined to the nervous system An interesting association has been shown to exist between intramuscular injections such as may be given for purposes of immunisation and the development of paralysis in neighbouring muscles during succeeding weeks This is now believed to be due to the action of poliomyelitis virus determined by the specific local trauma of the injection

Pathology —The virus of poliomyelitis is an obligatory intracellular parasite and its action takes place entirely within the nerve cell The changes seen in the nervous system vary with the virulence of the infection The virus has a special affinity for the anterior horn cells of the spinal cord and in severe infections these cells in portions of the cord undergo acute necrosis If the experimentally infected animal be destroyed at this initial stage no lesions other than these cell changes are found and the rapidly ensuing cellular exudation and meningeal infiltration seen in fatal human cases are not present But the necrosis of nerve cells in the surviving patient is naturally soon followed by phagocytic processes and amœboid (microglial) cells and polymorphonuclear leucocytes rapidly invade the affected areas and clear away the dead nerve cells It is essential to bear in mind however that these processes are secondary and not as used to be thought the primary and essential lesion of poliomyelitis In less severe infections less acute forms of nerve cells changes are seen and with these the cellular exudation is almost wholly of amœboid microglia cells These phagocytic cells fill the perivascular spaces in the affected parts of the cord Together with

leucocytes these cells finally overflow into the cerebrospinal fluid They may appear here even before the development of paralysis and it was this early indication of meningeal infiltration that led to the view formerly held that a meningitis preceded the involvement of the nervous system In the affected regions of the grey matter of the ventral horns some cells always remain unaffected by the virus Some degree of encephalitis is a constant feature although it is not usually clinically manifest

Lesions in the viscera have been described namely, hyperplasia of the lymphoid tissue and splenic enlargement—but these are not constant and their presence at the final stage of the malady is of uncertain significance

Cerebrospinal fluid—The fluid is clear colourless or faintly yellow and under normal or only slightly increased pressure and the titre of chlorides and sugar is normal The protein content is slightly increased at first and tends to rise during the first 3 weeks after the onset of the disease The cell content of the fluid is very variable In the majority of cases there is a pleocytosis of 20 to 100 cells per c mm but there may be more The count is usually a mixed one with lymphocytes outnumbering the polymorphs in a proportion of two or three to one In some cases however a high proportion of polymorphs may be found at the onset usually giving place to a predominantly lymphocytic increase in subsequent punctures The fluid may be normal in indubitable cases The nature and number of the cells seem not to afford any prognostic indications

Blood—In the early stages of the malady there is usually a polymorphonuclear leucocytosis which may reach as high as 30 000 This leucocytosis disappears when the fever abates

Symptoms—It is now generally believed that infection with poliomyelitis virus is a much commoner event than was formerly supposed and that of those so affected only a relatively small proportion develop symptoms of a kind sufficiently definite to permit of a clinical diagnosis Of these latter probably not more than a fifth are destined to develop paralysis This has led to the recognition of three degrees of poliomyelitis viz (*a*) formes frustes abortive cases or the minor illness (*b*) pre paralytic and non paralytic poliomyelitis (*c*) paralytic poliomyelitis This clinical subdivision is justifiable and useful on practical grounds but it should be understood that there is no corresponding pathological subdivision and that the three degrees shade off imperceptibly into one another

(*a*) *Formes frustes or the minor illness*—Such cases occur sporadically and are particularly plentiful in times of epidemics They can rarely be diagnosed with certainty although their nature may be suspected in the presence of an epidemic or retrospectively when other cases have occurred in the same family or isolated community The symptoms consist of malaise headache mild fever aching in the back and limbs and sometimes a sore throat or mild gastro intestinal upset and are thus common to influenza the pre eruptive stages of the exanthemata and such virus diseases as infective hepatitis or glandular fever The disturbance subsides in 24 to 48 hours without residual symptoms and the spinal fluid if examined is usually normal

(*b*) *Non paralytic and pre paralytic poliomyelitis*—The symptoms are essentially the same as in the minor illness but rather more intense and prolonged The onset is often abrupt and fever practically invariable The temperature is commonly 103° or 104° F and this pyrexia commonly lasts for 2 to 4 days and then gradually subsides sometimes finally and sometimes to rise again a few days later and before the paralysis makes its appearance Pains in the back and limbs are more severe and flexion of the spine is painful Vomiting and anorexia are common and in many cases there is slight diarrhœa After a day or so the general headache becomes intensified and occipital in position and is associated with the classical symptoms of meningeal irritation namely irritability neck stiffness and photophobia The muscles of the back and limbs are often tender and may show tremor and depression or loss of their reflexes There may be retention of urine

Such a clinical picture in an adolescent or young adult in the summer or early autumn is extremely suggestive of poliomyelitis but to those who have had extensive experience of epidemics the picture seen in young children is highly characteristic Draper has given a vivid account of this stage from which the following account is taken The child is commonly flushed and miserable and may be drowsy, but it presents a typical appearance of mingled apprehension and restlessness and may be very irritable In severe infections the child breathes rapidly appears preoccupied and in a state of tenseness An ataxic tremor and involuntary muscular jerkings may be present. Extreme fearfulness and confused and alarming dreams are common The child is hypersensitive to even the lightest touch and resents being moved Vomiting probably of central origin may also be present Headache pain in the neck and back stiffness of the spine and pain in the back on active or passive flexion, diminution of tendon jerks and some diffuse weakness all appear in sequence

During this stage of the illness it is impossible to predict with certainty whether the symptoms will gradually subside or whether paralysis will suddenly declare itself and if the nature of the disease has been recognised an agonising period of waiting is inevitable and may be prolonged for 2 or 3 days

Generally speaking severe fever and meningeal signs and depression of tendon reflexes are of grave significance but mild premonitory signs may be followed by severe local or general muscular paralysis It should be remembered that probably not more than one fifth of the cases diagnosed and in many cases confirmed by C S F changes subsequently develop paralysis

(c) *Paralytic poliomyelitis* —In these cases usually at the height of the constitutional and meningeal disturbance muscular paralysis declares itself It may be confined to the muscles innervated by the spinal cord—the spinal form—or affect those innervated by the bulbar nuclei either exclusively or in addition to spinal paralysis—the so called bulbar poliomyelitis or polio encephalitis

1 SPINAL FORM —The onset of paralysis occurs usually between the second and the fifth days of the constitutional disturbance but may be delayed as long as the tenth day if the fever persists From the moment of its first appearance it usually reaches its height within 24 hours but in rare cases it may continue to become more severe for several days or recrudesce after becoming stationary

In distribution and severity the paralysis varies over the widest possible extent At one end of the scale are those cases in which within a few hours all four limbs are completely paralysed and the patient is engaged in a life and death struggle with respiratory failure At the other are cases so mild that the paralysis is not recognised till the patient starts to get up Generally speaking the legs and lower trunk muscles suffer more frequently and severely than the upper parts of the body especially when diarrhœa has been a feature of the invasive period

Wherever it occurs the paralysis is of the flaccid lower motor neurone type with loss of muscle tone loss of voluntary power varying from weakness to complete paralysis and diminution or loss of the corresponding tendon reflexes This is rapidly followed by wasting which in severe cases is rapid and intense in degree Until it has been seen the rate at which the muscles dissolve under one s eyes can hardly be believed Such muscles are frequently tender and sometimes show spasm so that the development of contractures occurs both easily and rapidly The paralysis is generally much more widespread and severe at its commencement than it is destined to be permanently At first all four limbs may be completely helpless and later there may be complete recovery in all but one limb The widely spread temporary paralysis is due to a recoverable affection of nerve cells whereas the permanent paralysis is the result of actual destruction of nerve cells by the necrotic lesion Usually the muscles first affected are the ones that show the greatest permanent damage

In the rare ascending type the paralysis may gradually ascend from the legs and lower trunk to the upper limbs and progressive deterioration of the respiratory

muscles during the first day or two after the onset of paralysis is relatively common and is probably due to progressive exhaustion of the nerve cells of the upper thoracic and cervical region themselves a little damaged by the failure of the lower thoracic muscles to carry their share of the respiratory burden In cases where the cervical cord is involved respiratory embarrassment makes its appearance early and in the absence of artificial respiration in some form it may lead to a fatal outcome within a few hours of the onset of paralysis

In cases which survive the narrowing down of the initial paralysis begins to show itself after the end of the first week and any muscle which will recover useful power will have done so before the end of the third month The paralysed muscles undergo atrophy which is more rapid and complete in those cases in which there will be no subsequent recovery they give the reaction of degeneration They are flaccid from the first and in the course of time tend to develop a variable degree of contracture and yet it is common to see a limb which remains permanently flail like Any muscle which shows a response to faradism 3 weeks after the onset will usually recover completely When a limb is paralysed there is usually a considerable degree of vasomotor paralysis, and there may be subsequent retardation of growth Considerable deformities of the body and limbs may arise as the result of the loss of support which results from the paralysis from the action of unopposed muscles and from the contractures Such deformity may involve actual dislocation of joints as in the shoulder joint when the deltoid is paralysed and the pectorals escape

The local lesion of the spinal cord is by no means confined to the grey matter and may occasionally involve the contiguous white matter of the lateral column sufficiently to give rise to signs of lesion of the pyramidal tract and in rare cases of lesion of other neighbouring tracts such as the spino thalamic tract, with a result in a Brown Séquard s syndrome of pyramidal deficiency upon the same side and loss of pain and temperature sense on the opposite side below the lesion This is the so called ' myelitic form Paralysis of the cervical sympathetic is occasionally seen when the lower part of the cervical enlargement is involved with the usual signs of a small pupil and low lying lid on the affected side It is however, generally a transient event

Disturbances of sensibility of an objective kind are rare and are almost always transient, and amount to blunting of pain and temperature sensibility from involvement of the spino thalamic tracts which are contiguous to the ventral horns Subjective disturbances are common and consist of severe local pains in the limbs, back and neck Tenderness of the muscles and pain on moving the joints are sometimes very prominent and may persist for many weeks The dominance of the clinical picture by persistent pains in the periphery constitutes the so called neuritic' form of poliomyelitis

The reflexes both superficial and deep are at first lost in the affected region and indeed are generally absent throughout the body in the early stages of a severe case, from the general effect of the virus upon the nerve elements In the later stages they return or remain permanently absent according as the muscles recover or not The preservation of a tendon jerk or any sign of a returning reflex either deep or superficial in the early days of the illness is a most useful prognostic indication that the muscles concerned with the reflex will entirely recover

Retention of urine is common during the first 10 days of the illness particularly in the case of male subjects where the trunk muscles are involved It is never permanent

2 Brain stem Form or Bulbar Poliomyelitis —Involvement of the muscles innervated by the bulbar nuclei may be present from the onset and may be encountered in the absence of spinal cord symptoms This is commonly seen in the cases occurring as a complication of tonsillectomy More often however it occurs as an extension of the disease in cases in which the cervical enlargement of the spinal cord is involved and respiratory complications are already present Its onset is often

heralded by mental confusion and drowsiness acceleration and irregularity of the pulse irregularity of the respiratory effort and flushing and congestion of the skin and conjunctivæ These symptoms may be confused with those of anoxia Excessive bronchial secretion occurs and adds to the danger of this grave complication Paralysis of the pharynx may be unilateral or bilateral and leads to dysphagia and to the accumulation of secretions in the pharyngeal recesses Laryngeal paralysis may be partial or complete and may lead to dangerous adductor spasm Paralysis of the tongue may occur The palate is commonly involved giving rise to a nasal speech and regurgitation of fluids down the nose Unilateral or bilateral facial palsy is common but similar paralysis of the muscles of mastication is much more rare but occasionally the patient may be unable to keep the jaw shut Ocular paralyses are very rare and patients showing them are usually moribund Occasionally however spontaneous nystagmus occurring in short bursts and at a rapid rhythm may be seen and is not of particularly sinister significance

The occurrence of bulbar symptoms is always an event of grave prognostic significance but if the patient survives the cranial nerve paralyses make a remarkably complete recovery

Diagnosis —When once paralysis is present the diagnosis of poliomyelitis seldom presents much difficulty In children a localised paralysis has to be distinguished from such causes of ' *pseudo paralysis as acute rheumatism osteomyelitis syphilitic* epiphysitis and scurvy with subperiosteal hæmorrhage In all these there may be associated fever and general disturbance with pain and reluctance to move the limb

In cases of generalised paralysis the group of diseases most likely to be confused with poliomyelitis are the peripheral neuritides particularly acute infective polyneuritis and acute porphyria In both of these the paralysis is symmetrical and at first peripheral in distribution and although slight some sensory disturbances are usually present The finding of a C S F with a high protein content but no excess of cells is a point in favour of polyneuritis Cases of poliomyelitis affecting both legs and the lower part of the trunk may easily be confused with acute compression of the spinal cord in the dorsal region with a flaccid paraplegia especially when this is caused by an infective lesion of the spine such as osteomyelitis Careful attention to the history and the finding of sensory loss with a clear upper level will usually suffice to avoid this mistake

Isolated bulbar poliomyelitis may be confused with focal lesions of the medulla such as syringobulbia or vascular lesions and a very similar picture may be seen in botulism

It is particularly in abortive cases and in the pre paralytic stage that difficulty in diagnosis arises Indeed it is often impossible to diagnose poliomyelitis with certainty though it may be suspected in the presence of an epidemic or on account of the time of year

In cases showing merely fever malaise and some generalised muscular pains the differential diagnosis is from influenza tonsillitis and the exanthems These are rare in summer and early autumn More difficult to distinguish are the premonitory phases of certain other virus diseases namely infective hepatitis glandular fever and *virus pneumonia*

When signs of meningeal irritation are prominent the diagnosis is from the various forms of meningitis though it should be borne in mind that all the conditions mentioned above may be associated with meningism

The pyogenic meningitides usually present a picture so definite that serious difficulty does not arise but meningococcal meningitis may start insidiously and tuberculous meningitis relatively acutely The distinction from these conditions can usually be made with certainty on the cerebrospinal fluid but this may take a day or two

Greater difficulty occurs with benign lymphocytic meningitis and with the meningo encephalitis of mumps which may precede the parotitis as in both cases a pleocystosis

similar to that of poliomyelitis occurs with no fall in glucose, or chlorides and little increase in protein

The meningeal reaction to a cerebral or extradural abscess may also give a mixed pleocytosis with a sterile fluid but here there is usually a considerable increase in the total protein content

Course and Prognosis—A good deal has already been said on these aspects of poliomyelitis in the foregoing paragraphs In abortive cases and non paralytic cases which represent the vast majority of the total, recovery is complete though patients will often notice general lassitude and even a marked loss of weight for some weeks or months after the illness

Purely local paralysis presents no threat to life and the patient recovers with a varying degree of local disability It is not uncommon to see cases of complete paralysis of all muscles below one knee or of one shoulder girdle and spinal deformities may later develop from involvement of portions of the spinal musculature

Cases of generalised paralysis are always in grave danger because of the likelihood of involvement of the respiratory musculature and this complication is the principal cause of death However if the emergency is surmounted remarkable recovery of respiratory function occurs In part this is due to the development of increased efficiency in the remaining respiratory muscles including the accessory muscles but partly to the fact that the initial loss of power in diaphragm and intercostals is often due to exhaustion rather than to irreparable anterior horn cell damage

In cases surviving the first impact of the disease improvement in muscle tenderness begins after a week or so and recovery of function of muscle begins about the same time It usually begins first in the muscles last affected and in cases destined to make a good recovery it continues at a rapid rate for 2 to 3 months Recovery of tendon reflexes or the faradic response often precede the return of voluntary power Muscles which show no sign of recovery and have the reactions of degeneration at the end of this time are unlikely to make any useful recovery After 3 months recovery continues at a gradually slower rate for another 6 months but most of the improvement during this period results from the development and adaptation of function in already active muscles rather than from further recovery of nerve cells

In all but very mild generalised cases some degree of permanent wasting and weakness of muscles will remain which may necessitate the use of various appliances to improve function and mobility and various orthopædic procedures to the same end In severe cases the patient may be left permanently confined to a spinal chair or wholly dependant for life upon some form of respirator and he is faced with all the problems of psychological readjustment that this implies

In young children and to a less extent in adolescents the loss of muscle may lead to serious defects of growth in the limbs and to deformities both of the limbs and the trunk

The occurrence of bulbar symptoms increases greatly the gravity of the prognosis but if the patient survives the cranial nerve palsies usually undergo complete recovery

Second attacks of poliomyelitis occur but are exceedingly rare They probably result from a susceptible individual encountering at different times strains of the virus which do not confer cross immunity

Treatment—The first problem that faces a physician called to see a case of poliomyelitis is disposal Should the patient be left at home or moved to a hospital and if the latter to what hospital ? In abortive and pre paralytic cases this decision is a difficult one If on balance the diagnosis seems likely to be poliomyelitis and particularly if the existing symptoms are severe the decision should be for immediate transfer as a respiratory emergency may arise suddenly at any time If the case is mild or the fever already subsiding it may be justifiable to leave the patient at home In that case absolute bed rest should be enjoined for there is satisfactory evidence that the taking of vigorous physical exercise in the pre paralytic stage may not only

greatly increase the likelihood of paralysis occurring but may also determine its distribution The child should remain in bed for 2 weeks after all fever and symptoms have subsided and get about gradually during the third week Contact with other children should be avoided for 3 weeks after the temperature becomes normal and for the same time the excreta should be immersed in lysol for 12 hours before disposal No restrictions need be placed on diet though at first the appetite is usually poor

If it is judged that the diagnosis is probable or beyond doubt—and this will include all paralytic cases in the acute stage—the case should be transferred to hospital and is notifiable The choice of hospitals may in this country at least present a difficult problem From the public health point of view admission to a fever hospital where facilities exist for complete isolation is the disposal of choice and is the accepted policy of the Public Health authorities From the patient s point of view this may also be satisfactory in large cities where sufficient cases occur to make it a practical proposition to assemble together the trained nursing staff the experienced medical officers and consultants and the wide range of instrumental equipment needed to deal with the many emergencies that may arise during the course of a case of poliomyelitis But in smaller centres and in the country fever hospitals are not so provided and are often unsuited to cope with acute cases of this disease The alternative to a fever hospital is a well equipped general hospital Here cases can be nursed either in isolation cubicles or with barrier precautions the standard of nursing is usually high and the full range of consultant and specialist assistance both for the acute and convalescent stages is available Under such circumstances transmission of the disease to nurses medical officers or other patients is exceedingly rare and in the view of most of those in a position to judge, a general hospital is to be preferred to all but the best fever hospitals for such cases

The ideal solution of the problem is the setting up of regional poliomyelitis centres where a specially trained staff both medical and nursing is immediately available and all instruments and equipment are kept permanently ready for use

Whatever the hospital in which the case of poliomyelitis is treated it constitutes a potential emergency of the most dramatic kind Treatment falls into three natural phases

(*a*) The acute illness lasting from the onset for 2 or at most 3 weeks
(*b*) The stage of neuronic recovery lasting for 6 months or so from the onset
(*c*) The stage of adaptation and rehabilitation lasting up to 3 years from the time of the acute illness

(*a*) *The acute illness* —Here the primary object of treatment is to ensure the patient s survival He should be nursed on a soft mattress or air bed upon a stiff wire bed or fracture boards All excreta linen and feeding utensils should be sterilised and kept separate from those of the other patients and all attendants should wear masks and gowns The diet should be light but as nutritious as the patient will tolerate

All muscles showing weakness or paralysis should be put as far as possible in the *position of physiological rest The feet and toes should* be supported at right angles to the legs by pillows and a vertical board The knees should be maintained at 10 flexion by a slender bolster underneath them If the deltoids are affected the shoulders should be kept abducted by pillows to as near as the patient will tolerate to 90 The hand should be dorsiflexed at the wrist to 30 with the fingers and thumbs gently flexed round a small woollen cushion Pain and spasm in muscles may be relieved by hot packs and the discomfort may necessitate the use of aspirin or other analgesic and even of morphine provided that this is not contraindicated on other grounds From the beginning all joints should be put through their full range of passive movement twice a day and the complete immobility formerly insisted upon is now regarded as harmful and responsible for much of the painful limitation of

movements at joints and muscular contractures which can be such a tiresome feature of the convalescent phase Retention of urine is best treated by an indwelling catheter and seldom lasts more than 2 weeks even in severe cases If cystitis develops it should be treated immediately by means of sulphonamides or the appropriate anti biotic and, if severe this should be combined with tidal drainage and bladder washouts

The complications of poliomyelitis which threaten life are respiratory failure and bulbar involvement.

Respiratory failure —Although this commonly develops suddenly during the first 2 or 3 days of paralysis it does not do so without warning Frequent and careful examination of the chest may reveal the progressive involvement of the intercostal muscles on one or both sides and may be confirmed by asking the patient to count aloud without drawing breath An initial count of 50 or more may fall to 20 before the patient is conscious of dyspnœa at rest Spirometer readings should be taken at regular intervals and starting at 3000 to 4000 ml may fall on successive measure ments to 1200 ml or so before cyanosis is visible or subjective distress is experi enced

It is often the involvement of the diaphragm which precipitates a respiratory crisis and necessitates the use of some sort of artificial respirator If the emergency develops suddenly as it often does within 12 hours of the onset of paralysis the decision to use the respirator presents no difficulty If it develops gradually over several days from progressive exhaustion of the remaining respiratory muscles a difficult choice has to be made There is a natural reluctance to submit a sick person to the terrifying experience of dependance for life upon a machine but it should be remembered that this experience is much less of an ordeal if it occurs before it is obligatory Further more, throughout the period of gradual respiratory failure the lungs are undergoing a process of lobular collapse and if atelectasis occurs it takes some days to re expand the collapsed areas even with adequate respiration Generally speaking therefore it is preferable to resort to a respirator too early rather than too late and a rapidly falling respiratory exchange as indicated by a vital capacity of less than 1500 ml in an adult is an indication for the use of a respirator

The effects of respiratory embarrassment are often aggravated by the accumula tion of bronchial secretions frequently excessive in amount which the patient is unable to cough up This complication can often be forestalled especially in children, by postural drainage The patient is laid face downwards on a thoracic bed with the head and chest sloping downwards at 30 to 45° In other cases it may be necessary initially to suck out the secretions through a bronchoscope

A number of artificial respirators are available for choice That of most general application is the Drinker respirator and its various modifications in which the entire patient except for his head is enclosed in an airtight tank The air in this is rhythmic ally sucked out by bellows operated by an electro motor in such a way that the negative pressure so created draws air into the patient s thorax A sorbo rubber collar secures an airtight fit round the neck and portholes are provided for nursing and inspection The whole floor of the tank carrying the patient can be drawn out for more prolonged attention

The tank respirator gives satisfactory results when properly employed but certain risks are associated with its use Secretions in the trachea and bronchi are liable to be drawn into the alveoli ventilation can be too deep or too rapid with consequent disturbance of the blood chemistry or it may be insufficient and so give rise to pro gressive anoxia The motor may break down and an efficient engineer is as much a part of the team in a respirator unit as efficient nurses and doctors The patient s colour pulse and subjective sensations are a better guide to the efficiency of respiration than blood gas analyses

Of other respiratory aids available some operate by negative and some by positive

pressure Various cuirass respirators which may be useful for transport act by suction but enclose the thorax only The Bragg Paul respirator consists of a distensible jacket which encloses the chest and rhythmically expresses the air from the chest relying as does manual artificial respiration upon the elasticity of the chest wall to re expand the lungs

Recently positive pressure machines operating with a face mask such as is used in closed circuit anæsthesia have been introduced and are particularly useful in combination with the Drinker respirator for enabling the patient to remain out of the tank long enough for nursing care and physiotherapy Whatever type of respirator is used the personalities and training of the attendants are of paramount importance and every effort should be made to avoid frequent changes in personnel

Bulbar poliomyelitis —When this occurs in the absence of respiratory involvement or of widespread mesencephalitis it is a relatively benign condition Dysphagia may necessitate feeding by nasal catheter and the accumulation of secretions in the nasopharynx and upper respiratory passages may necessitate postural drainage or repeated suction The occurrence of adductor spasm of the vocal cords may require tracheo tomy Recovery is the rule Bulbar poliomyelitis with mesencephalitis and signs of more generalised polioencephalitis is usually a terminal event in a moribund patient

It is when it occurs—as it usually does—as a complication on the second or third day of a case of spinal poliomyelitis of the cervical and thoracic cord with respiratory involvement that bulbar poliomyelitis presents a therapeutic problem of the greatest difficulty It is associated with excessive bronchial secretion and often with laryngeal obstruction which with a patient already in a respirator has usually led to rapid death In a recent epidemic in Denmark where such cases were common the mortality was nearly 90 per cent until the drastic measure of immediate tracheotomy and positive insufflation followed by regular suction was adopted This procedure reduced the mortality to approximately 25 per cent but the method makes the greatest possible demands upon medical and nursing attendance and is clearly only possible in specially developed centres With the modern methods outlined above it is not uncommon for a patient to survive the immediate emergency only to become permanently de pendant upon artificial respiration—a dilemma of a most poignant kind for all concerned

(*b*) *The stage of neuronic recovery* —During this period which lasts for 3 to 6 months in severe cases the objects of treatment are to promote the maximal recovery of nerve cells and therefore of muscles to restore function and to prevent contractures and deformities The patient is best treated in a specialised convalescent unit such as is often associated with orthopædic centres Massage and passive movement of limbs should gradually give way to active movements carried out at first with slings or in warm baths and later against progressively increasing resistance Weight bearing should be assisted by such devices as bannisters crutches and calipers Such devices as stationary bicycles and boats and the intelligent use of ball games play an important part and progress is more rapid in cheerful and well run units where group methods are possible and the elements of competition and emulation can be made use of

Care must be taken to prevent the development of deformities and where the trunk muscles are involved the patient should spend several hours a day lying prone on a flat bed to correct the tendency to develop a lower thoracic and lumbar kyphosis Breathing exercises should be given

After 6 months it is unlikely that more neurones will recover their function and improvement becomes much slower It continues however for many months or even years by virtue of the increased adaptation of the patient to his disability and by the hypertrophy and taking over of new function by existing muscles

(*c*) *The stage of adaptation and rehabilitation* —This is really a continuation of the

above and may last 2 to 3 years In it function gradually improves and the patient's range of activity increases Instrumental devices may be used and in many cases the patient has to be trained for a new occupation depending upon the nature of the residual paralysis and the natural aptitudes of the individual After 2 years operative orthopædic procedures may be needed to stabilise flail joints or to improve function by tendon transplants

Specific Treatment —The virus of poliomyelitis is not susceptible to any of the existing antibiotics or other known drugs As early as 1910 Netter tried to minimise the extent or severity of the paralysis by injecting convalescent human serum but without success In spite of claims to the contrary, all subsequent attempts to affect the acute illness by antisera have proved useless This is in conformity with what occurs in other virus diseases of the nervous system and it has been shown that in experimental poliomyelitis in order to prevent the development of the disease after the injection of virus into the nervous system the immune serum must be injected within 12 hours of the injection of the virus

PROPHYLAXIS —In view of the generally accepted observation that tonsillectomy may precipitate bulbar poliomyelitis this operation should not be carried out during epidemics of the disease Similarly injections of immune sera or inoculations against diphtheria should be avoided Much progress has been made in recent years in the field of immunisation against poliomyelitis Passive immunisation by means of serum or gamma globulin can play at best only a limited part in the prevention of the disease Active immunisation with killed virus on the other hand offers better hopes of protection and has been used extensively in the United States and other countries The Salk formalin inactivated polyvalent vaccine received an initial set back in 1955 when over 200 cases of poliomyelitis in the United States were attributed to its use but stricter safety standards for its manufacture and testing have since been imposed and millions of children have been inoculated without mishap Active immunisation has also been achieved by giving suspensions of live attenuated virus by mouth to human volunteers Virulent strains can be rendered avirulent by frequent passage through mice or cotton rat brain while retaining their antigenic quality The results however although encouraging are still *sub judice*

PRECAUTIONS IN SCHOOLS —A common problem arises when a case of poliomyelitis occurs in a boarding school and medical advice is sought by the school authorities or the children s parents It should be borne in mind that at present medical knowledge is insufficient to give an entirely satisfactory ruling in the matter We do not know exactly how long an individual continues to pass virus in his excreta or droplets nor do we know fully how the infection is spread or how the virulence of the virus and the susceptibility of individuals may be measured Furthermore such is the fear of the disease in the public mind that parents cannot be expected to behave entirely rationally with regard to it

If more than one case occurs in a school the best course is to put the school as a whole in isolation All intercourse with other schools should be cancelled the pupils should be confined within bounds vigorous games and swimming should be suspended and any child developing mild symptoms should at once be confined to bed in the sanatorium Ideally the school should not be dispersed as it is likely that the majority of the pupils have already come in contact with the source of infection and may themselves be a source of danger to others The arbitrary period of 3 weeks is usually accepted for isolation Unfortunately the majority of parents will insist upon removing their children and this cannot be prevented Parents should be advised to notify their own practitioner immediately on the child s return home and he should be kept away from other children and from such places as swimming pools cinemas etc for 3 weeks Again, strict bed rest should be enforced if any mild febrile disturbance should show itself

VASCULAR DISORDERS OF THE NERVOUS SYSTEM

ARTERIAL THROMBOSIS AND HÆMORRHAGE

Cerebral thrombosis and cerebral hæmorrhage seem hitherto to have been described in textbooks of medicine as quite separate conditions almost antagonistic and mutually incompatible between which it was possible and even highly essential to make a differential diagnosis for the purpose of applying very dissimilar lines of treatment in the respective conditions each line of treatment being the worst possible for the other condition It cannot however, be too forcibly pointed out that primary arterial thrombosis and primary arterial hæmorrhage depend in every case upon degeneration of the arterial wall and that every condition of degeneration of the arterial wall may cause either thrombosis or hæmorrhage indifferently It is a usual experience to find in patients who have had several strokes that thrombosis was the cause of the earlier and hæmorrhage of the final apoplexy Even in that condition which has always been held to be the most important antecedent of cerebral hæmorrhage—renal disease with high arterial tension—thrombosis and not hæmorrhage is the cause of apoplexy in many cases On account therefore of the identity of the underlying pathological condition in every case and the clinical association of thrombosis and hæmorrhage of the cerebral arteries and the difficulty of distinguishing them clinically the two conditions are here described together

Ætiology and Pathology —The arterial degeneration which may result in cerebral thrombosis and hæmorrhage is due to the following causes (1) Arteriosclerosis which is the common cause both of thrombosis and of hæmorrhage in the second half of adult life and which is by far the most frequent cause of hæmorrhage It must be especially borne in mind that cerebral atheroma may be local in the cerebral vessels and unassociated with general atheroma of the systemic vessels (2) Syphilis which was formerly the commonest cause of thrombosis in the first half of adult life and which is less frequently the cause of hæmorrhage It may affect both the large and the small arteries even to the smallest All the coats of the artery are affected and in the finest vessels there is conspicuous lymphocyte accumulation or cuffing round the vessel (3) Periarteritis nodosa Buerger s disease and other less common varieties of arterial disease (4) Abnormal conditions of the blood especially when associated with heart failure as in septicæmic conditions Hæmorrhage into the brain may also complicate polycythæmia and acute leukæmia (5) In association with new growths of the brain both thrombosis and hæmorrhage are common events especially when the neoplasm is soft and rapidly growing The vascular lesion may occur quite early in the course of the new growth and apoplexy may be the first sign of its presence (6) Inflammatory conditions of any nature may cause thrombosis and hæmorrhage The vascular lesions are usually small but they may be extensive and may cause death (7) Traumatic lesions such as the passage of a bullet through the brain or a blow upon the head or concussion from high explosives may cause extensive thrombosis or hæmorrhage (8) Cerebral hæmorrhage results often enough from the direct rupture of a true aneurysm or angioma or of one of those irregular local thinnings of the vessel wall which is called a false aneurysm and may take place from an artery the wall of which is softened by disease though there be neither thinning nor bulging of the vessel wall

Syphilitic cerebral thrombosis is not usually a pure pathological process for the vascular disease is often accompanied by acute syphilitic encephalitis with much lymphocyte extravasation in the vicinity of the diseased vessels and acute local œdema which increase the ischæmia when thrombosis occurs The symptoms of loss of

cerebral function are not all due to the thrombosis but are *in part due to the recoverable* acute inflammatory condition and it is for this reason that syphilitic apoplexy often shows much more recovery than do other varieties

Thrombosis is a more common cause of apoplexy than is hæmorrhage but it is much *more frequently survived while hæmorrhage is frequently fatal* within from a few hours to a few days of its onset It follows therefore that in the necropsy room of a general hospital hæmorrhage *is seen much more often than is thrombosis* while in infirmaries where the survived cases of apoplexy collect, thrombosis is almost *invariably the lesion found to be responsible* for the apoplexy

Thrombosis tends to occur when an habitually high blood pressure is temporarily lowered and the circulation less active, and is always strongly suggested when apoplexy occurs during sleep and conditions of quiet, and after exhaustion exposure to cold severe purgation and in debilitated states generally It is preceded by slowing of the circulation in the area affected and this may be productive of prodromal symptoms Or there may be slight local thromboses preceding the main thrombosis also giving rise to prodromal symptoms Thrombosis may thus have an ingravescent onset especially when clotting occurs in distal branches of an artery and extends towards the main vessel, but on the other hand it may have an absolutely sudden onset when the clotting occurs primarily in a large artery The immediate effect of the thrombosis is a condition of infarction with œdema extending widely in the vicinity and it is this œdema which causes the loss of consciousness so commonly seen a few hours after the apoplexy has occurred The œdema tends to pass off in a few days and the area bereft of circulation by the thrombosis tends to become narrowed by collateral circulation from surrounding regions and any recovery of function within the affected region must be by collateral circulation from elsewhere In many cases however—perhaps the *majority* of those which are clinically ascribed to cerebral thrombosis—actual thrombosis does not occur but cerebral tissue to which the circulation has been inadequate *for a long time eventually undergoes* softening rather abruptly There is little essential difference between the two groups of cases and it *is customary to apply the term* cerebral thrombosis *to all* *The affected* area at an early stage is bright red in colour and soon becomes soft and shrunken (red softening) *Later the blood pigments degenerate with the production of* bilirubin and are partly absorbed producing a yellow coloured lesion (yellow softening) Finally much of the softened tissue *becomes necrotic and is absorbed leaving one or several* cystic cavities These cavities are never so sharply defined as those resulting from embolism *because of the more complete necrosis occurring with the later lesion* *Still* a severe arterial thrombosis occurring at an early age may result in a porencephaly Cavities *found in cases of apoplexy after years have elapsed* are too often *attributed to* hæmorrhage in reality they are nearly all due to thrombosis The cerebrospinal fluid in thrombosis is never *found to contain blood but some little time after the* apoplexy it is often coloured yellow or yellowish brown from escape of changed blood pigments when the lesion has reached the *surface of the convexity or the surface* of the ventricle and pleocytosis may be found after a recent softening

Hæmorrhage which is usually described as an apoplexy *of sudden onset may* be so when the escape is from a large vessel When the bleeding commences from a smaller vessel the symptoms *are not sudden in their onset* but gather *rapidly* Such a hæmorrhage is much like an avalanche Commencing from a small vessel the hæmorrhage tears a small cavity *and in so doing opens up fresh bleeding points* and with increasing destruction more and more bleeding occurs from every piece of torn tissue until the hæmorrhage reaches such a size as *to burst commonly into the* ventricle and much more rarely on to the surface Indeed it is difficult to conceive how a hæmorrhage into such a soft and vascular tissue as is the *brain should* ever stop As a matter of fact it rarely does so but causes death in the first attack of hæmorrhagic apoplexy within from a *few hours to a few days after the* onset from widespread

tearing up of the nervous tissue and bursting into the ventricle One of the most important clinical distinctions between apoplexy due to thrombosis and apoplexy due to hæmorrhage is that the former is often survived and that the latter is almost invariably fatal within a short time of the onset

Hæmorrhage may occur anywhere within the nervous system but its common seat of commencement is in the centrum semiovale and the vessel which bursts is one of the perforating arteries of which the lenticulo striate which carries the name of the artery of hæmorrhage is the most common Such bleedings are often called capsular hæmorrhages It must be pointed out that this term capsular refers to the region outside the corpus striatum or external capsule and not to the compact internal capsule as it converges to the crus cerebri The cerebrospinal fluid in cases of hæmorrhage contains blood within a very short time of the onset

While both thrombosis and hæmorrhage may occur in any part of the brain the semi-oval centre the calcarine region and the pons are the common sites of both of them in that order of frequency Hæmorrhage is rare except in these regions while thrombosis is not uncommonly met with elsewhere

Symptoms —The nature of the symptoms in apoplexy will depend upon the site of the vascular lesion and as the semi oval centre is the commonest site and as many arteries supply the fibres of the pyramidal tract in different parts of its course hemiplegia is the common result if the lesion is in the left hemisphere some degree of aphasia is commonly associated with the hemiplegia

Thrombosis of the *anterior cerebral artery* in its distal portion causes paralysis and postural sensory loss in the contralateral leg but if the vessel is thrombosed proximal to the origin of the artery of Heubner—which supplies part of the anterior limb of the internal capsule—the contralateral arm and face are also affected so that hemiplegia results The *middle cerebral artery* is rarely thrombosed as a whole except in syphilitic cases which are now uncommon thrombosis of the whole of this artery causes such extensive destruction in the corresponding cerebral hemisphere that the most severe hemiplegia with postural loss and hemianopia results accompanied by severe aphasia if the lesion is on the left side Both of these arteries may be involved when thrombosis occurs in the *internal or common carotid artery* The frequency of this condition has been disclosed by arteriography In such a large artery the clot is at first mural and portions of it may break off and cause emboli in branches of the derived arteries When the lumen of the internal carotid artery becomes completely obstructed the anterior and middle cerebral arteries continue to receive blood by way of the circle of Willis and even the ophthalmic artery which takes origin just before the bifurcation usually receives a blood supply sufficient to prevent the occurrence of blindness in the corresponding eye While the middle and anterior cerebral arteries may remain patent the blood supply to them through the circle of Willis may be inadequate and especially in elderly subjects successive softenings of greater or less degree may therefore occur in the hemisphere of the affected side It is consequently not uncommon for two or more incidents of partial hemiplegia to occur with intervals of days or weeks or even months between them The severity of the clinical pictures that may result from carotid thrombosis is consequently subject to very great variation but in quite a number of cases the paralysis is surprisingly slight and it is only by arteriography that the condition can be confidently diagnosed In the worst cases, however all the arteries derived from the internal carotid may be thrombosed and the condition may be fatal in the acute stage In some instances both internal carotid arteries have been found to be occluded and these have usually been cases of dementia There is evidence that the thrombosed carotid artery may become recanalised A considerable number of the patients who suffer from carotid thrombosis are men in the first half of life and trauma to the neck may be an important ætiological factor in older patients the condition is usually associated with atheroma

When the *posterior cerebral artery* is thrombosed the outstanding sign is contra lateral *hemianopia with sparing of the fixation point*

Pontine apoplexy involves the appearance of motor and sensory hemiplegia—first on one side and then on the other with the onset of coma, involvement of cranial nerve nuclei *e g* with loss of lateral movements of the eyes—may be the first sign

Cerebellar apoplexies and thrombosis of the *posterior inferior cerebellar artery* produce acute ataxia with forced movements and vomiting (p 1440)

The onset in hæmorrhage is almost always rapid and may be sudden, in thrombosis it may be sudden or ingravescent with embolism it is always instantaneous Consciousness is lost or not, according to the severity of the initial lesion and the site it occupies and to the magnitude of the processes which follow the initial lesion namely the œdema of embolism and thrombosis and tearing of the brain tissue in hæmorrhage In hæmorrhage consciousness is lost soon and the rapid development of severe symptoms which progressively deepen is a most important early indication that this is the nature of the lesion In calcarine thrombosis the initial symptoms may be so slight as to pass unnoticed by the patient whose first indication of defect may be that he runs into objects on his blind side Convulsion sometimes occurs at the onset and this nearly always indicates thrombosis rarely embolism and never hæmorrhage There may be some local spasm in the region of the cranial nerves in pontine hæmorrhage, but this is not convulsion

Conjugate deviation of the eyes is a common feature of all apoplexy When the lesion is irritative at its onset, and not too destructive and always when convulsion occurs at the onset there may be active conjugate deviation the eyes being turned away from the side of the lesion and towards the paralysed or convulsed side in *hemiplegic cases or the blind side when hemianopia is present* But this active conjugate deviation lasts but a short while and is followed by a paralytic conjugate deviation in the opposite direction both eyes being directed away from the paralysed side and towards the side of the lesion This variety of conjugate deviation may last for a considerable time but usually disappears with the onset of deep coma

The pupils are often unequal they may be contracted or dilated widely and may be insensitive to light In severe apoplexy when as the result of the cerebral shock or when hæmorrhage or œdema has so raised the pressure as greatly to reduce the physiological activity of all the intracranial elements with the production of deep coma the pupils are widely dilated and insensitive In pontine lesions the pupils are often contracted to pin point size and this condition is of important localising significance

In proportion to the severity of the general intracranial disturbance respiration tends to be hurried noisy and stertorous and with increasing pressure to become irregular grouped or of the Cheyne Stokes type The blood pressure tends to be raised and the pulse full in all conditions of apoplexy provided the heart will respond to the requirement of an increased blood pressure in the face of an increased intracranial pressure Swallowing is often impossible and the sphincters may be relaxed or retention may occur

In the usual variety of apoplexy where the lesion is in the area of the middle cerebral artery and the local sign of the lesion is hemiplegia it will be obvious that when the general intracranial pressure becomes severe and the coma becomes deep the hemiplegia becomes less apparent or masked by the universal condition of paralysis consequent upon the general intracranial condition The physician often sees the patient for the first time when there is considerable coma and he must determine upon which side the lesion is situated and endeavour to have some perspective as to prognosis by determining the severity of the lesion

The following points will serve to determine the side of the lesion when these signs are present (1) The paralytic conjugate deviation is towards the side of the lesion (2) The corneal reflex when any is present is diminished or lost on the

hemiplegic side (3) Painful stimulation will elicit less response or no response upon the hemiplegic side (hemianæsthesia) (4) The patient may respond by blinking to a feint made with the observer s hands towards the patient s eyes upon the sound side and not on the hemiplegic side (hemianopia) (5) The limbs on the hemiplegic side when raised and allowed to fall passively do so in a more lifeless inert and flaccid fashion than upon the sound side (6) And when there is any difference between the knee jerks abdominal reflexes and plantar reflexes the former tend to be diminished and lost on the hemiplegic side while the plantar reflex will be of the extensor type on the hemiplegic side It must be remembered in this connection that a severe lesion of one cerebral hemisphere abrogates for a time at least most of the functions of the whole hemisphere and that the hemianæsthesia and hemianopia here referred to do not necessarily indicate that the destructive lesion involves the visual and sensory paths And further that the condition of coma due to increased intracranial pressure of itself causes such signs as bilateral loss of abdominal reflexes and knee jerks and bilateral extensor responses in the plantar reflex

The severity of the lesion may be judged—(1) From the depth of the coma (2) from the degree to which the patient responds to any form of stimulation and from the general signs of nervous depression present—for example a condition of complete bilateral flaccidity with complete loss of all reflex action and of all response to stimulation indicates a most severe lesion and (3) from signs of failure of respiration as shown by irregular grouped or Cheyne Stokes breathing It is further important to arrive at a determination if possible as to whether the condition present is stationary deepening or showing signs of amelioration

Vomiting is not an uncommon occurrence in the early hours of apoplexy and before coma becomes deep Hyperpyrexia is often seen in fatal cases before the end It is especially common and may reach a high degree in pontine apoplexy It may be preceded by initial depression of temperature It is of fatal prognostic import

Hemiplegia is the commonest sequel of vascular lesions of the brain The signs which serve to indicate its presence in the comatose subject have already been enumerated After cerebral thrombosis it may happen that the initial hemiplegia is completely recovered from but unless this recovery begins early and progresses rapidly it is not likely to be complete The essential feature of hemiplegia is the loss of voluntary movements on one side of the body, but as this loss begins to pass off certain new features make their appearance These are muscular hypertonus increased tendon jerks and associated movements

The restoration of movements follows a certain order Deviation of the tongue and facial asymmetry clear up early next the leg begins to recover and finally—and often very incompletely—the arm The return of movements in the limbs is selective In both upper and lower limbs movement at the proximal joints recovers first and most completely In the leg extension and plantar flexion recover more completely than flexion and dorsiflexion As a result the patient can often stand when he cannot lift the foot and leg to step properly and has instead to circumduct the limb when walking In the arm flexion movements recover first and best while the fine skilled movements of the hand and fingers are frequently lost for ever

The development of hypertonus or spasticity is as selective as the return of movements In the leg the extensor group of muscles becomes spastic in the arm the flexor group Thus the arm tends to take up a position of adduction with flexion at elbow wrist and digits The leg is always spastic in extension and does not go into flexion contracture as may happen in spastic paraplegia from spinal cord lesions The degree of hypertonus varies and is greatest when the loss of movement is greatest

The tendon jerks are exaggerated and there is clonus (knee and ankle) in the affected limbs The Babinski plantar response persists, but the abdominal reflexes which are initially lost on the affected side sometimes return after a period of months

The forced immobility of shoulder and distal joints in the arm may lead to the formation of adhesions

The so called associated movements are involuntary changes of posture of the paralysed limbs which accompany forceful voluntary movements, or such involuntary movements as yawning

CEREBELLAR APOPLEXY —This is usually the result of thrombosis of the posterior inferior cerebellar artery which is a branch of the vertebral artery and the clinical picture is very unlike that of cerebral apoplexy *The patient is seized with a sudden* intense vertigo which throws him to the ground, as in Ménière s disease Incessant vomiting and forced movements follow the forced movements rotating the patient, so that he comes to rest prone, with that side of the face corresponding with the side of the cerebellar lesion in contact with the pillow There is intense ataxy usually *bilateral at first and later becoming confined to the limbs and trunk on the side of* the lesion The patient is unable to lift his head, or to maintain the sitting or standing position When placed in such a position he positively dives to the ground when released Nystagmus with the long slow movement to the side of the lesion and a short fast movement in the opposite direction is conspicuous and the skew deviation *of the eyes is sometimes seen* There is much general hypotonia of limbs and trunk which soon becomes limited to the side of the lesion Head retraction, pain and stiffness of the neck and opisthotonos may occur When the patient s condition recovers sufficiently to allow of examination all the signs of a unilateral cerebellar lesion will be found Consciousness is not often lost Since the posterior inferior cerebellar artery also supplies the lateral region of the medulla signs indicative of disturbance of this region are usually present and these may dominate the clinical picture rather than the cerebellar signs Chief amongst them are analgesia and ther manæsthesia of the face and head due to implication of the as yet uncrossed quinto thalamic path and of the limbs and body upon the opposite side due to involvement of that part of the spinothalamic tract which has crossed below this level Between these two areas of sensory loss there is often a gap where sensibility is normal corre sponding with that part of the spinothalamic tract which is crossing obliquely at this level and therefore is too near the middle line to be affected Paralysis of the motor vagus is often found from involvement of the nucleus ambiguus and from the exten sion of the lesion or of consecutive œdema towards and across the middle line it sometimes causes severe dysphagia and dysarthria and one of the great dangers of this form of apoplexy is extension of the thrombosis to that part of the medulla which contains the respiratory and other vital centres When however, such extension does not take place, and if the destruction of the lateral lobe is not too extensive the most remarkable recovery may take place

Diagnosis —*The nature of the lesion* —Thrombosis should be diagnosed not withstanding the presence of high arterial tension or renal disease in all cases of apoplexy without organic cardiac valvular disease when the onset occurs during sleep or under circumstances of quiet depletion or exhaustion, and in all cases where prodromal symptoms are marked or where the onset of the apoplexy is gradual and in apoplexies occurring in advanced age for then hæmorrhage is almost unknown All slight apoplexies and nearly all those that survive the first 10 days after the ictus are due to thrombosis Thrombosis should be diagnosed in all primary apoplexies in young syphilitic subjects, and in this connection the serum reaction and the cytology and reactions of the cerebrospinal fluid are all important in the diagnosis

Puerperal apoplexy is mostly due to thrombosis of cerebral veins (see p 1452)

The cerebrospinal fluid affords important indications since hæmorrhage into the brain in most of the cases soon leaks on to the surface or into the ventricle If blood is absent from this fluid a few hours after the ictus thrombosis or embolism is highly probable and *hæmorrhage is very unlikely* Any infarction coming to the surface may in the course of time cause the fluid to be blood tinged or yellow It is

important to bear in mind that the infarct conditions of embolism and thrombosis are followed by packing of the infarcted region with polymorphs and that these may escape from the surface in such numbers as to load the cerebrospinal fluid with such a high polymorph pleocytosis as to suggest the presence of suppurative meningitis

Hæmorrhage is a likely cause of apoplexy occurring during exertion especially if it occurs at a moment of severe physical strain or at the height of passion It is always a probable lesion in cases where a previous thrombotic apoplexy has occurred the final event where multiple strokes have succeeded one another being almost invariably hæmorrhage An apoplexy with rapid onset and with symptoms rapidly deepening with a quick onset of deep coma and the development of pyrexia and signs of respiratory failure is usually due to hæmorrhage The certain test that an apoplexy is due to hæmorrhage is the presence of blood in quantity in the cerebro spinal space as proved by lumbar puncture In cases of chronic nephritis and malig nant hypertension where the blood tension is very high, and where there is severe retinitis hæmorrhage is the most likely cause of stroke

Embolism should be diagnosed in all cases in which there is an obvious cardiac valvular lesion particularly mitral stenosis septic endocarditis aortic disease or aneurysm It is true that syphilitic cerebral thrombosis may occur with syphilitic aortitis but the combination is rare for syphilitic aortitis usually occurs at a much later age than does syphilitic cerebral thrombosis

The position and extent of the lesion —The position of the lesion may be judged by the nature of the initial signs whether visual sensory motor or aphasic cerebellar or pontine and later by the permanent symptoms resulting from the lesion It must be carefully borne in mind in this connection that a severe lesion of a cerebral hemi sphere may entirely abrogate the functions of that hemisphere during the acute stage initially by a process of shock and afterwards by the occurrence of œdema in the vicinity of the lesion which may spread widely The extent of the lesion may be gathered by the severity or otherwise of the early symptoms and their rate of increase, and by early or immediate loss of consciousness and by the completeness of the paralysis resulting The more severe the extent of the lesion the sooner do grave signs of general cerebral failure appear

Differential Diagnosis —The diagnosis of coma due to a cerebral vascular lesion is usually made without difficulty from the history and from the presence of un equivocal signs of local lesion of the brain In a patient without history and when the coma has become so deep as to remove the unilaterality of physical signs the diagnosis may be difficult from other causes of coma such as uræmia and diabetes poisoning by opium alcohol and its derivatives and coal gas and in cases of difficulty search is to be made for the usually obvious signs of these conditions Uræmia may present especial difficulties for it is often associated with cerebral vascular lesion and transient hemiplegic attacks may occur in this condition This is true also of the crises of essential hypertension which are described in more detail on p 1444 Absolutely sudden death which is so often recorded in death certificates as due to apoplexy is usually associated with cardiac infarction Apoplexy never causes sudden death There is one recorded case of death from cerebral hæmorrhage in 5 minutes but it is rare in any apoplexy for death to occur in less than 2 hours Other conditions causing hemiplegia with coma must be taken into consideration Epilepsy especially when the convulsion is unilateral may be followed by marked unilateral paralysis (Todd s paralysis) which may last for a considerable time Here the history of recurring attacks and the complete recovery will easily prevent confusion

Cerebral malaria and heat stroke may closely resemble apoplexy and should always come to mind when rapid coma follows the development of cerebral symptoms in circumstances where these causes are likely The congestive attacks of general paralysis of the insane are peculiarly difficult to diagnose from apoplexy and especially

so when occurring as the initial manifestation of the disease These attacks take the form of rapidly occurring attacks of hemiplegia aphasia hemianopia, hemianæsthesia or of some combination of these conditions usually associated with initial convulsions and followed by coma The diagnosis of a syphilitic thrombosis is made with reason because of the positive serum reactions and cerebrospinal fluid examination If energetically treated the patient recovers with rapidity and completeness It is the too rapid recovery in a case of apparent syphilitic thrombosis which should suggest the possibility of the stroke being a congestive attack in general paralysis of the insane

In all cases of coma without history, especially when there are signs of local cerebral involvement a careful examination of the head should be made for traces of recent injury

Prognosis—In thrombosis due to atheroma the apoplexy may be rapidly fatal from extension of the thrombosis and secondary œdema In cases which survive considerable recovery may occur in proportion to the extent of the lesion but in these subjects an apoplexy is usually the beginning of the end since the underlying pathological causes arterial disease and failing cardiac action still exist and are not amenable to any radical treatment It is astonishing however how many of the cases of apoplexy *due to atheromatous thrombosis survive for years without any recurrence of the thrombosis* or occurrence of hæmorrhage A majority of the cases of apoplexy from syphilitic thrombosis make a fair recovery which obviously depends upon how much permanent thrombosis occurs in the lesion of acute syphilitic encephalitis which is responsible for this condition and upon the early application of appropriate treatment for syphilis In some of these cases even, no recovery occurs

In cases of hæmorrhage the immediate prognosis is the gravest possible the great majority of the cases surviving but a few hours

Treatment—When arterial disease is known to be present, the only measure which can in any way tend to safeguard the patient from apoplexy is moderation in all things in diet alcohol mental and physical exercises and above all moderation in all measures tending to cause marked variation in blood pressure It is highly probable that no treatment influences the course and fatal issue of apoplexy due to hæmorrhage Thrombosis and embolism however allow some scope for treatment which should be the same in the two conditions and as medical treatment in cases of hæmorrhage is useless and cannot avert the fatal result one line of treatment may be recommended in all cases of apoplexy

Absolute rest is in the first place, essential when prodromal symptoms appear Restlessness may be combated with bromides If the patient is conscious he should make as little effort as possible His head and shoulders should be raised special care being taken that the neck is not bent and that nothing shall interfere with the return of blood from the head If there is unconsciousness with stertor the head and shoulders should be turned upon one side so that the tongue does not fall back and impede respiration Purgation should be avoided and the bowel relieved at intervals by enemata Food in a liquid form should be administered at regular intervals and if there is any difficulty in swallowing the food should be administered with the nasal tube The bladder should be carefully watched from the first, lest retention should occur and the catheter passed when necessary Lumbar puncture should when necessary be performed for diagnostic purposes, and it frequently gives relief from symptoms due to the high intracranial pressure Bed sores and hypostatic bronchitis must be avoided by the usual measures In the cases that survive the first few days passive movements should be used daily to all the joints of the affected side in hemiplegic cases for this will obviate the painful residual adhesions which form in the joints of the paralysed limbs, and especially in the shoulder joint and subsequently cause so much pain and misery to the patient With the return of the power of voluntary movement active exercises take the most important place in treatment The final stage of hand and finger movements depends

not alone on the severity of the damage done to the brain but in part upon the thought given to devising active exercises for it and the assiduity with which the patient can be persuaded to employ them To avoid fatigue it is best to ordain a given daily period of some minutes for systematic exercise A rubber sponge of appropriate size fixed in the palm by a strip of webbing passing round the hand will limit the passive flexion of the fingers and will provide a resilient resistance against which the patient may move his paretic digits Massage is an adjuvant but never a substitute for active exercises in the patient who can undertake them Electrical stimulation of the muscles is absolutely contraindicated It has no other effect than to aggravate the spasticity that is so serious a hindrance to free movement A hemiplegic patient after apoplexy, should be got upon his legs and encouraged to make attempts to walk as early as ever the returning power allows any possibility of the attempt

GENERALISED CEREBRAL ATHEROMA

Ætiology and Pathology—For the ætiology and pathology of atheroma the articles on pp 835 919 should be consulted In many subjects the cerebral arteries are affected at an earlier age and more severely than any others in the body Males are the victims of generalised cerebral atheroma more often than females and the symptoms though most common in the sixties and later, are recognisable in the more severe cases soon after the age of 50 The brain is the seat of innumerable minute vascular lesions There are numerous small softenings on its surface and the cerebral cortex becomes thinned in consequence of degenerative changes In the central parts of the brain especially in the basal ganglia small cysts develop from the softenings and eventually a mesh like condition—the status lacunatus—may result

Symptoms—The onset of this condition is insidious and its course steadily progressive Mental or physical changes may predominate and both are liable to abrupt exacerbations which are to be attributed to small cerebral vascular lesions The mental symptoms are often noticeable first The patient s range of interests becomes reduced and intellectual activities of all kinds are gradually discarded Memory for recent events becomes faulty while that for events long past remains unimpaired Confusion is liable to occur and the patients become unable to adapt themselves to new circumstances and are obstinately conservative Emotional control becomes impaired and affective response may be inadequate Previously existing tendencies to anxiety or depression or paranoid traits may become exaggerated Confusion and lack of attention may lead to incontinence and disorders of dress Dysphasia is common and apraxia may also occur

The physical symptoms take the form of a slowly developing muscular rigidity which has been called pseudo Parkinsonism The facies becomes set movements become less free and in walking the step becomes gradually shortened until it may be only a few inches this *marche à petit pas* is very characteristic The patient becomes unable to relax his muscles and if as he lies in bed passive movements of the limbs are attempted by the examiner great resistance is encountered The grasp reflex may be discovered in one or both hands The tendon jerks are exaggerated and the plantar reflexes indefinite or weakly extensor

In some instances the most pronounced physical feature is a spastic paralysis of the muscles innervated from the pons and medulla and hence called pseudo bulbar-palsy The physical basis of this syndrome is uncertain the lesions concerned are bilateral and may be situated in the anterior parts of the internal capsules or possibly in the brain stem itself The facies becomes set voluntary movements of the lips are restricted the tongue is spastic and looks small and cannot be protruded beyond the teeth and movements of the palate pharynx and vocal cords are all

similarly limited The result is dysarthria of a degree which *may render the patient's speech unintelligible* together with difficulty in mastication and in swallowing (dysphagia) There is no muscular wasting The jaw jerk *is exaggerated The* lips may be held apart and the saliva trickles from between them Emotional movement temporarily inhibits the rigidity of the facies and is exaggerated as a consequence of the pyramidal impairment Moreover, in consequence of the bilateral pyramidal disturbance uncontrolled laughter or crying may occur and there is usually a tendency towards one or the other so that the patient who suffers *from uncontrolled* laughter may laugh even on hearing bad news and the patient who suffers from uncontrolled crying may weep when he is amused General atheroma is usually well marked and arterial hypertension may or may not be present The state of the retinal arteries is not a reliable guide to that of the cerebral arteries

Diagnosis —If mental symptoms predominate in the early stages the diagnosis will have to be made from general paralysis of the insane and the absence of characteristic signs of nervous syphilis, together with negative findings in the blood and cerebrospinal fluid will exclude the latter Other forms of pre senile dementia such as Alzheimer s disease (see p 1630) and Pick s disease (p 1629) are not associated with the same degree of motor disturbance as is usual in atherosclerotic dementia When physical symptoms predominate the presence of atheroma and signs of early dementia and usually the absence of tremor differentiate the condition from paralysis agitans When pseudo bulbar palsy is present, the diagnosis from motor neurone disease (amyotrophic lateral sclerosis) may be difficult but the complete absence of wasting the presence of rigidity in the facies and upper limbs and the association of atheroma are usually sufficient to make the distinction When arterial tension is high and changes in the optic fundi are present the picture may closely resemble one of cerebral tumour, and the differentiation depends largely on the presence of arterial hypertension and the extensive retinal lesions which distinguish neuro retinitis (hypertensive neuro retinopathy) from the papillœdema of raised intracranial pressure

Prognosis —The course of the disease is gradually downward and may at any time be terminated by a severe stroke ' but in general the patients survive for years and severe cerebral vascular accidents are uncommon among them In the end the patient becomes bed ridden and dies in consequence of an intercurrent infection or when he has reached a debilitated state from a terminal cerebral thrombosis

Treatment —This can only be symptomatic and the patient should be kept up and about as long as possible It is unfair and unwise to put too much dietary restriction on him and if he is a small or moderate eater no further limitation is required

HYPERTENSIVE ENCEPHALOPATHY

In a preceding paragraph on the differential diagnosis of apoplexy (p 1441) mention was made of the sudden and transient cerebral symptoms associated with essential hypertension and some further reference to them is necessary It is known that the subjects of this variety of hypertension may ultimately succumb to cerebral hæmorrhage but it should also be borne in mind that they are subject from time to time to what are known as hypertensive crises Similar attacks occur in acute nephritis and eclampsia The patient has a high blood pressure The attack is precipitated by a further rise in this and develops with intense headache sickness and sometimes drowsiness or even semi coma Examination will reveal the presence of hypertensive retinitis in most cases but in a proportion there is a definite papill œdema with retinal hæmorrhages and exudate Accompanying these symptoms there may be hemiparesis hemianopia focal or generalised fits or other indications of a local cerebral lesion The crisis is brief lasting from a few hours to several days and usually ends in recovery but recurrence is likely and finally many subjects develop

cerebral atheroma and succumb to cerebral hæmorrhage Intervals of several months may intervene between succeeding crises

The presence of papillœdema is taken to indicate that cerebral œdema is complicating the situation The transient nature of the crisis and particularly the rapid appearance and disappearance of such symptoms as hemiparesis exclude the possibility of arterial thrombosis or other material lesion of the kind and spasm of the arteries has been invoked to account for the symptoms There is no conclusive evidence that this occurs Yet while the cerebral arteries are not under the same measure of vasomotor control as arteries elsewhere in the body, it is known that some such control exists and it may be that in arterial hypertension more intense spasm is possible than in healthy arteries At least it may be said that no hypothesis better founded or more in harmony with the facts of clinical observation has been formulated

Differential Diagnosis —As has been indicated the transitory character of the symptoms excludes gross vascular lesions such as thrombosis and the same may be said of intracranial tumour and lead encephalopathy Yet it may be admitted that while it is present the hypertensive crisis shows many points of resemblance to the last two named conditions especially when papillœdema is found Plumbism in children and young persons not uncommonly develops with headache vomiting convulsions and focal signs and the development of an intense papillœdema sometimes also with high blood pressure and albuminuria and search for other indications of lead poisoning and careful history taking are necessary to exclude this condition In intracranial tumour the systolic blood pressure is rarely above normal limits the history is longer and the condition progressive Uræmia can usually be excluded since in essential hypertension the blood urea is within normal limits and the only abnormality in the urine may be a trace of albumin

Treatment —Venesection is indicated as the first step and when there is papillœdema or other signs of cerebral œdema (convulsions high cerebro spinal fluid pressure) lumbar puncture and the withdrawal of cerebrospinal fluid and also the intravenous or intramuscular administration of hypertonic solutions are necessary As a measure of urgency from 50 to 70 ml of a 50 per cent solution of dextrose or sucrose may be given intravenously For less urgent cases and as a measure that can be repeated for the relief of headache 6 oz of a 20 per cent solution of magnesium sulphate may be given per rectum at 6 hourly or less frequent intervals The convulsions may be treated by rectal administration of paraldehyde (240 to 360 minims in water) or by the hypodermic injection of gr 3 of soluble phenobarbitone in solution

The subsequent management of the case is that of the underlying essential hypertension it should be borne in mind that the use of potent detensive drugs in patients with diseased cerebral vessels is accompanied by a great risk of thrombosis

CEREBRAL EMBOLISM

Cerebral embolism is infinitely less common than thrombosis

Ætiology —The embolus may be (1) a fragment of blood clot (2) a vegetation or detached portion of one of the cardiac valves or in rare instances an atheromatous plaque (3) air bubbles or (4) globules of fat

(1) The commonest cerebral embolus is a detached fragment from a clot which has formed in the left auricle in a case of auricular fibrillation Less frequently it comes from a clot in the dilated auricular appendage in a case of mitral stenosis without fibrillation or from one on the inner surface of the infarcted ventricular wall after coronary thrombosis Other sources of clot emboli are aneurysms of the large vessels between the heart and the brain a clot covering an atheromatous ulcer in the first part of the aorta and clots which may form in the pulmonary veins and even in

the left heart in suppurative conditions of the lungs In exceptional cases a congenital heart lesion may provide a route by which emboli from the systemic veins can reach the brain without passing through the lungs—paradoxical embolism (see p 697)

(2) The emboli of the second group are most commonly small portions of infected vegetations from the cardiac valves in cases of subacute bacterial endocarditis In other instances larger emboli are formed by vegetations from acute bacterial endocarditis

(3) Air emboli are usually multiple They may occur in association with operations on the lungs and in the course of almost any operation in which a vein of medium or large size is opened While emboli of more solid character will not pass through the pulmonary capillaries it is probable that air emboli do so and consequently air emboli from almost any part of the body may reach the cerebrum. The commonest single cause of air embolism to day is probably damage to the surface of the lung by the needle in the course of producing or refilling an artificial pneumothorax and it occurs also during major operations on the lung It may follow insufflation of air into the vagina or it may occur in association with retained placenta and even as a result of division of veins during the operation of Cæsarean section

(4) Fat emboli are a cause of cerebral complications after fracture of one of the long bones and may cause death Like air emboli fat globules pass through the pulmonary filter

Emboli usually pass into the middle cerebral arteries or their branches because these are the direct continuation of the carotid arteries Very rarely the internal carotid is obstructed but if it is the circulation in its branches is usually maintained by the circle of Willis Next in frequency is the posterior cerebral artery, and then the vertebral Because of the mode of origin of the left carotid artery, emboli affect the left half of the brain more frequently than the right In a case of subacute bacterial endocarditis the cumulative effect of innumerable minute infected emboli may cause extensive softening in the left hemisphere at a time when the right hemisphere is little affected

Symptoms—The onset is immediate A stroke due to embolism is the most suddenly occurring of all the apoplexies and there are no prodromal cerebral symptoms Unless a large vessel such as the middle cerebral artery be occluded consciousness is usually not lost but a stuporose state may occur either with the onset or after a few hours, and may last several days Hemiplegia is the common physical syndrome and it may be of all degrees of severity according to the size of the cerebral lesion When emboli are numerous and of small size and particularly when they are infected as in subacute bacterial endocarditis the development of hemiplegia may be gradual

Diagnosis—Embolism should never be diagnosed unless there is evidence of cardiac disease aneurysm or some other recognised source of emboli but in the presence of such disease especially of auricular fibrillation it is the usual cause of any stroke which may occur The diagnosis should not be rejected simply becau e the manifestations of apoplexy are slight

Prognosis—In cases of auricular fibrillation the hemiplegia is in many cases not severe and good recovery is frequent but when a large vessel is occluded the hemiplegia is usually very severe and complete and it remains so Further embolism is likely to occur eventually In other cases the prognosis depends largely on the course of the causal condition which is responsible and whether the emboli are affected or not In cases of bronchiectasis for example, the emboli being infected generally give rise to multiple cerebral abscesses Puerperal cases of cerebral embolism in the absence of cardiac and other disease usually do well

Treatment—As far as the cerebral lesion is concerned treatment is the same as for thrombosis In most cases the condition responsible for the embolism calls more urgently for treatment and in cases of auricular fibrillation complete rest for

several weeks and appropriate treatment of the cardiac disorder is essential, in order to diminish the risk of further emboli occurring

INTRACRANIAL ANEURYSM

Aneurysms within the cranium are common and may conveniently be considered in four groups

(1) Minute atheromatous aneurysms of the arteries at the base of the brain are frequent and may be numerous in elderly subjects but only in rare instances do they cause symptoms The clinical disturbances to which they occasionally give rise result either from bleeding or from their pressure on and even adhesion to the adjacent ocular nerves, and are thus similar to those of the more important group which follows

(2) Of the remainder the great majority are berry aneurysms situated on or near the circle of Willis An aneurysm of this kind develops at a bifurcation of an artery in consequence of a congenital defect in certain individuals of the elastic lamina at this point It is thus not congenital but develops at the site of a congenital weakness The importance of berry aneurysms is that they may and frequently do rupture causing subarachnoid hæmorrhage Otherwise only a small proportion of them give any evidence of their presence Aneurysms situated on the posterior or lateral portions of the circle may interfere with the third cranial nerve giving rise to paralysis which is as a rule partial and which may be either gradual or sudden in its onset Less commonly aneurysms situated laterally on the circle compress the optic tract just behind the chiasma and so produce homonymous defects in the visual fields and in rare instances aneurysms on the anterior communicating artery cause pressure on the optic chiasma with consequent disturbance possibly of variable intensity in the central or temporal parts of the visual fields

(3) Aneurysms of the internal carotid artery are usually situated within the cavernous sinus Such an aneurysm may develop gradually or more commonly after an initial period of slow development it may dilate rapidly or even suddenly until it comes into contact with the wall of the sinus or again it may rupture into the sinus becoming an arterio venous aneurysm (see also p 929) Whether the development of the aneurysm be slow or rapid the various oculo motor nerves and the branches of the trigeminal nerve situated in the wall of the sinus become affected The patient experiences severe pain in one side of the forehead or in the forehead and cheek and if the onset is sudden he may vomit Double vision comes on rapidly and may proceed to complete paralysis of the third fourth and sixth cranial nerves but the paralysis is more often partial Ptosis is always a feature The affected eye may become proptosed When the lid is raised the patient may find that vision in the affected eye is impaired but in some cases within a few days the vision improves greatly and the pain passes off some ocular paralysis and proptosis usually remaining If the aneurysm is situated above the cavernous sinus (supra clinoid carotid aneurysm) the optic nerve may be affected by direct pressure and progressive visual impairment may be the first symptom By suitable radiographic technique erosion of the great wing of the sphenoid or of some part of the sella turcica may be demonstrated or some degree of calcification may be seen in the wall of the aneurysm Aneurysms of the internal carotid artery may be demonstrated also by arteriography In cases in which there is an arterio venous communication a bruit may be audible with the stethoscope either over the affected eye or over the carotid artery in the neck Such cases are frequently treated by ligation of the common carotid or of the internal carotid artery after a trial period of compression

(4) *Angiomatous Malformations* —The frequency of angiomas of the racemose or cirsoid type has been revealed by arteriography They occur most often in

the territory of the middle cerebral artery and are almost invariably arterio venous racemose aneurysms—that is to say instead of a capillary bed, a tangle of blood vessels is interposed between the arterial and venous systems the arteries feeding the malformation are hypertrophied and dilated and the veins draining it are dilated and pulsating and they contain arterial blood As most of the arteries enter the cerebral hemispheres from the surface these angiomata typically appear on the surface and extend in a sector, often with a roughly pyramidal shape deeply into the hemisphere and may reach to the ventricle Cerebral tissue is found between the vessels of the mass and cerebral tract evidently pass through it without being affected until hæmorrhage or thrombosis occurs There is some evidence that these angiomas gradually enlarge The vessels composing the angioma are not perfectly formed arteries but are vascular channels of very imperfectly differentiated structure for the most part they have very thin walls of irregular thickness composed chiefly of fibrous tissue with some fragmentary and irregularly distributed muscular coat and even wisps of elastic tissue in their walls

These angiomas threaten the lives of their hosts by hæmorrhage and the hæmorrhage may be either intra cerebral or extra cerebral (subarachnoid) or both It may occur at any age from childhood onwards and it is rare for an affected patient to reach middle age without having suffered a hæmorrhage In many cases fits of some kind local or general precede signs of hæmorrhage and sometimes occasional fits occur over many years A symptom which is typical but by no means constant is a systolic bruit it may be heard with the stethoscope all over the head or only over the carotid arteries and in most cases it is at times audible to the patient Headaches are common and occasionally are of a typically migrainous type and associated with vomiting, in other cases they are associated with a feeling of stiffness in the neck and are suggestive of slight leakage from the aneurysm Until hæmorrhage or thrombosis occurs there are usually no abnormal physical signs to be found on clinical examination When the combination of symptoms is suggestive arteriography is called for and the diagnosis is dependent on this procedure

In a special group of cases there is an external as well as an internal angioma the external manifestation being usually situated in the territory of the trigeminal nerve (Sturges Weber syndrome)

A considerable proportion of these malformations (other than the Sturges Weber group) are amenable to surgical removal or palliative ligation of vessels

In rare instances similar malformations occur in the brain stem and by reason of the aggravations which result from small hæmorrhages and the consequent remissions the clinical course of the patient s illness may be very similar to that of disseminated sclerosis

SUBARACHNOID HÆMORRHAGE

Synonyms —Spontaneous Subarachnoid Hæmorrhage, Meningeal Hæmorrhage

Bleeding into the subarachnoid space may be an accompaniment of head injuries and it may also follow intraventricular hæmorrhage but the usual cause of uncomplicated, or as it is sometimes called spontaneous subarachnoid hæmorrhage is rupture of a cerebral aneurysm on the circle of Willis or on one of its component arteries What has been called here the berry aneurysm may rupture suddenly and freely with the production of fatal apoplexy or there may be recurrent leaking of blood in small amounts from such an aneurysm, leading to a syndrome of meningeal irritation Whereas with cerebral hæmorrhage the bleeding occurs into the substance of the brain and the latter is severely and irrevocably damaged with subarachnoid hæmorrhage the blood is effused chiefly outside and over the surface of the brain and although there is still a risk that the immediate consequences of the apoplexy may be equally disastrous if the event is survived the chances of full recovery are infinitely greater

(1) *The apoplectic syndrome*—The patient may have been subject to frequent headaches or the episode may be quite unheralded until a sudden intense headache rapidly followed by sudden lapse into unconsciousness signals the free rupture of the aneurysm It may be thought that an ordinary cerebral hæmorrhage has occurred when the comatose patient is first seen but in uncomplicated subarachnoid hæmorrhage examination reveals no evidence of hemiplegia On the other hand a bilateral Babinski plantar response will be obtained and there will be marked neck rigidity At first both pupils may be small and sluggish but in fatal cases the pupils ultimately dilate Examination of the optic *fundi* may reveal sub hyaloid hæmorrhage or papillœdema Lumbar puncture produces a fluid that resembles pure blood

Recovery from hæmorrhage of this severity is by no means uncommon In fatal cases death commonly ensues within 24 to 36 hours or at some time during the first fortnight from fresh bleeding If this period be safely passed the prognosis as to recovery becomes good The course of the illness may however be prolonged The patient gradually recovers from coma taking possibly many days to regain full and continuous consciousness The temperature rises after 24 hours and remains at 99 5 or 100 F for about a week and the urine may contain abundant albumin and some sugar—either of which may lead to an erroneous diagnosis if the possibility of its occurrence be not known

Headache is intense and may last for 2 or 3 weeks with irritability and some stiffness of the neck The knee jerks or ankle jerks or both are commonly abolished a few days after the onset but they return after a further week or two and in slighter cases sooner The patient who has recovered from his coma shows at first little intellectual activity but answers rationally and briefly when questioned A few weeks later however he is liable to manifest psychotic disturbances of the Korsakoff type having no recollection of his visitors when they come again and giving them confabulatory accounts of his imaginary doings which show that he is disorientated in place and time This disturbance soon passes off completely and in some cases is almost ephemeral and the patient eventually regains his full intellectual powers

From such a severe illness not every patient rises unscathed Focal damage may be caused either by the hæmorrhage or by subsequent clotting If the aneurysm lies close to or partly embedded in the brain its rupture may cause considerable cerebral laceration which if not fatal may leave partial hemiplegic weakness If the aneurysm be at the bifurcation of the basilar artery clotting in or around it may give rise to thrombosis in one of the branches entering the brain stem with resultant motor or sensory hemiplegia of the opposite side of the body associated possibly with oculo motor paralysis on the side of the new lesion Oculo motor palsies also arise from involvement of the nerves in clot and strabismus is perhaps the commonest residual defect

(2) *The meningitic syndrome*—In this case the hæmorrhage is less abundant and therefore consciousness may not be lost There is violent headache restlessness delirium rigidity of neck and spine Kernig s sign bilateral extensor plantar re sponses and sometimes diplopia and squint Within a few hours or somewhat later ophthalmoscopic examination may reveal the presence of flame shaped hæmorrhages in the nerve fibre layer of the retina or massive hæmorrhage in the sub hyaloid space The last named is characteristic of subarachnoid hæmorrhage A low grade papill œdema is occasionally also observed

In small leaking hæmorrhages the cerebrospinal fluid is more or less heavily bloodstained and may for 2 or more weeks be discoloured yellow or brownish according to the amount of blood originally present

(3) *The lumbago sciatica syndrome*—This uncommon condition first described by Hall commences with pain and stiffness in the lumbar region followed by pains in the legs and sometimes the leg jerks are absent Pyrexia is the rule The diagnosis

depends upon the characteristic cerebrospinal fluid of subarachnoid hæmorrhage The explanation of this syndrome is not clear and it is probable that in some cases at least the source of the hæmorrhage is in the spinal canal

Differential Diagnosis —The recognition of subarachnoid hæmorrhage is an easy matter in those cases in which the train of symptoms calls at once for the examination of the cerebrospinal fluid and blood is found in the fluid Prior to lumbar puncture the distinction from other varieties of cerebral hæmorrhage can often be made (1) by the age of the patient practically all hæmorrhagic apoplexy in the first half of life being the result of ruptured aneurysm and (2) by the history of preceding symptoms such as headache diplopia ophthalmoplegia and migrainous phenomena Arteriography performed as soon as the patient is well enough may demonstrate the aneurysm

Prognosis —When the aneurysm ruptures frankly and widely and the bleeding can be free the outlook is hopeless, and death occurs in from a few minutes to a few hours nor does drainage avert the consequences of so large an opening into a main arterial trunk If as so commonly happens there is a slower leakage which perhaps is intermittent the outlook will depend (1) upon the cessation of the bleeding and the healing of the leak by clotting and (2) upon the possibility of the free escape of the effused blood into the subarachnoid space In many of the cases of subarachnoid hæmorrhage the bleeding ceases and healing of the aneurysm by clotting and calcification, occurs with complete recovery In other cases there may be repeated attacks of leaking at intervals of weeks months or even years and again, many of such patients make good recovery in the end

Treatment —In the case of subarachnoid hæmorrhage the patient must be kept absolutely at rest with the administration of sedatives An immediate injection of morphine is indicated when the patient is not comatose and has the usual intense headache It may be necessary also on the recovery of consciousness on account of headache and restlessness In general repeated lumbar puncture is inadvisable as it may lead to recurrence of hæmorrhage but if there be signs of raised or of rising intracranial tension (and progressive slowing of the pulse is generally a reliable indication of this) then lumbar puncture may be expedient When recovery sets in the patient should still be kept in bed for at least 4 and possibly 6 weeks During the first fortnight recurrent hæmorrhage is more likely to occur than later during the course of convalescence When the aneurysm is appropriately situated ligation of the common carotid artery of the same side is sometimes performed and in a few instances the neck of the aneurysm itself has been ligated or clipped

CHRONIC SUBDURAL HÆMATOMA

Synonym —Pachymeningitis Hæmorrhagica

Ætiology —This condition is a consequence of hæmorrhage from veins The latter name now superseded expressed the belief that it was inflammatory and it was supposed that it was more or less confined to chronic alcoholic subjects and sufferers from general paralysis of the insane

It is now known that the lesion is traumatic in origin and is the result of venous hæmorrhage Falls especially those on the forehead or occiput not at the time apparently productive of serious injury may yet cause tearing of the cortical veins as they pass from the surface of the brain to enter the dural sinuses The tear is commonly in the subdural space on one or both sides of the vertex Thereafter blood leaks from time to time from the torn veins and collects on one or both sides of the vertex external to the arachnoid membrane Though by no means unknown in young subjects this type of lesion is much commoner in patients over 50 years of age

Pathology—The periphery of the clot formed tends to organise so that a fine capsule is built up round the hæmatoma The latter remains liquid in its centre, and such hæmatomas may reach a large size The underlying cerebral hemisphere collapses in a peculiar way downwards and medially and the brain stem is thereby pushed over to the other side so that the margin of the crus which contains the pyramidal tract may be indented by the free edge of the tentorium against which it is pressed As a result of this interference with the pyramidal tract of the opposite side a hemiparesis may be caused on the side of the hæmatoma

Symptoms and Diagnosis—The difficulty which still frequently surrounds the diagnosis of subdural hæmatoma depends in large measure upon a general unawareness that it is a not uncommon lesion and from a survival of the old and now obsolete notion that its occurrence is largely confined to sufferers from the two affections named above It must be emphasised again therefore that subdural hæmatoma may follow an apparently trivial head injury in persons at all age periods that essentially its symptomatology is that of a space occupying lesion with a feature characteristic of hæmatoma namely a remarkable fluctuation in the course and severity of the symptoms that owing to the frequently bilateral nature of the lesion the signs are apt to be difficult of localising interpretation and finally that in the presence of such a blurred picture a history of head injury some days weeks or even months before the onset of symptoms should always give rise to the suspicion that a hæmatoma and not a new growth may be present

There is almost invariably a latent period in the development of a subdural hæmatoma This may vary from a matter of days to one of weeks or months On the whole it may be said that in young persons the latent period is apt to be shorter and the symptoms more severe and of more rapid evolution than is commonly the case in elderly subjects In young subjects too there is usually no difficulty in obtaining a history of head injury either a fall upon the head or a blow sustained at sport or in some other way The initial symptom is usually headache fluctuating in intensity apt to be most severe on awaking in the morning or on physical exertion With the passage of days or weeks this becomes more severe and soon other symptoms are added to it The patient has days on which he is drowsy He may pass rapidly into stupor or even coma emerging again to become almost normal Transient accesses of diplopia with squint may be noted Examination during a period of maximal symptoms may reveal a papillœdema sometimes severe in rapidly developing cases The plantar responses may on one or both sides be of the extensor type There may be an inequality of tendon jerks on the two sides the abdominal reflexes may be diminished on one or both sides They may even be absent Periods of mental confusion may also occur In most instances there is no trace of blood in the cerebrospinal fluid

The fluctuation in the severity of the symptoms the fugitive character of the physical signs and the generally downhill tendency of the illness despite the fluctuations are amongst the features which are characteristic of subdural hæmatoma and help to differentiate it from that of intracranial new growth When the syndrome develops rapidly it is more common to meet a marked slowing of the pulse than in new growth

Simple radiographic examination of the skull usually shows nothing more than marked displacement of the pineal shadow to one side or laterally and downwards but if the patient s condition be not so critical as to forbid it examination after injection of air into the theca (by the lumbar or cisternal route) reveals the outline of the hæmatoma and of the deformed cerebral hemisphere while cerebral arteriography gives a striking and characteristic picture that is diagnostic

In all cases there is a great liability to a rapid development of coma with a fatal issue Yet the occasional finding at necropsy of what is clearly a subdural hæmatoma of very long standing unsuspected during life shows that from time to time the

sequence of events briefly reviewed above fails to develop It must, however be confessed that even in such cases it is highly probable that careful clinical examination and an awareness on the part of the examiner of the symptom complex of hæmatoma might have made diagnosis possible during life

Treatment—The features which should make clinical diagnosis possible have been described but in the absence of arteriography certainty can be obtained only by an exploratory operation This consists in bilateral trephine holes and tapping of the subdural space, and if necessary in the turning down of osteoplastic flaps and the evacuation of the cyst when found It is clear that treatment is essentially surgical

THROMBOSIS OF CEREBRAL SINUSES AND VEINS

Thrombosis of the cerebral sinuses or veins may occur as a primary condition or it may be secondary to infective processes spreading to the sinuses from contiguous infected regions

Ætiology—Primary thrombosis is a rare condition It is said to affect the superior longitudinal sinus most commonly It is more common in the first year of life than at any other period when it may follow diarrhœa bronchitis or the conditions of exhaustion met with in tuberculous disease and in congenital syphilis, and it may follow acute diseases, such as measles diphtheria etc It may also occur at any age up to advanced old age, in the terminal stages of cancer pulmonary tuberculosis and other chronic diseases It occurs in the puerperium the antecedent confinement usually having been quite normal and similarly it may occur after abortion

The essential cause of secondary thrombosis is the advent of micro organisms to the sinuses The infection is often a mixed one but the common organisms present are streptococcus pneumococcus and *Bacillus coli* The sinus may become infected as a part of a general pyæmia or infection may spread directly through its wall from a focus of local disease most commonly from an extradural abscess due to ear disease or frontal sinusitis In most cases however the sinus becomes infected from a local spreading septic thrombosis of the veins which open into the sinus from an infected spot at a distance Thrombosis of sinuses may also occur from injury as by bullet wounds and fractures of the skull and may also result from surgical procedures in the region of the sinuses

In the condition known as *otitic hydrocephalus* (see p 1404) a sterile mural clot or deposit of fibrin beginning in the lateral sinus above an infected middle ear extends into the superior longitudinal sinus or spreading sterile clot may obstruct both lateral sinuses and consequent interference with the absorption of cerebrospinal fluid gives rise to hydrocephalus

Pathology—The affected sinus if filled with clot is distended and bulging and feels to the touch as if it were injected with a solid mass In many of the non infected cases, however the clot does not fill the sinus This applies particularly to the superior longitudinal sinus, where there may be extensive mural clot with retention of a blood channel One or several veins draining into the sinus may become obstructed and thrombosed and in cases in which the sinus is filled with clot all the veins entering it may suffer blockage and thrombosis Thrombosis of a vein causes intense congestion of the convolutions which it drains and a moderate degree of subarachnoid hæmorrhage due to rupture of the small tributary veins The underlying brain softens on its surface and later a saucer shaped depression is left at the site The cavernous and lateral sinuses do not drain the brain directly and blocking of one of them does not cause so much cerebral disturbance as obstruction of the superior longitudinal sinus Thrombosis of the cavernous sinus may however extend to the ophthalmic veins and cause blindness and at the same time the nerves which lie in its outer

wall—the third the fourth, the ophthalmic division of the fifth and the sixth nerves—may be paralysed

In the infective forms the clot very quickly breaks down into pus, and general pyæmia results or the spread of infection along a tributary vein may give rise to a cerebral abscess

Symptoms—Many cases are infective and the clinical picture is greatly complicated by (1) the presence of infective disease in relation to the cranium e g in the ear and especially by (2) the onset of pyæmia The symptoms due to thrombosis of individual sinuses or of cerebral veins are more easily recognised in the non infective or primary cases

Superior longitudinal sinus—This sinus has two functions (1) it is a channel into which drain the veins from the upper and medial surfaces of the cerebral hemispheres and (2) by the Pacchionian bodies associated with it it forms part of the mechanism by which the cerebrospinal fluid is absorbed into the blood stream Complete obstruction of the sinus by a clot gives rise to (*a*) extensive bilateral venous thrombosis on the surface of the brain with resulting spastic paralysis of the legs and upper arms the hands and face being spared and (*b*) increased intracranial pressure and in most cases some degree of papillœdema In many cases however the clot does not obstruct the sinus Mural clot may obstruct one or more of the entering veins and thus give rise to hemiplegia which may or may not be ushered in by convulsions or again bilateral paralytic phenomena of any degree may occur There may be associated drowsiness or coma On the other hand the veins may not be obstructed and the clot may be so situated as to interfere with the absorption of cerebrospinal fluid through the Pacchionian bodies paralytic phenomena are then absent and the disturbance is limited to the manifestations of raised intracranial pressure—headaches papillœdema and in some cases vomiting In otitic hydro cephalus the symptoms of this group alone are present

Lateral sinus—It is doubtful whether aseptic thrombosis of one lateral sinus gives rise to any symptoms *provided the other one is of normal size and communication* at the torcular is free Since the superior longitudinal sinus usually turns into the right transverse sinus obstruction of the right lateral sinus may produce a moderate degree of hydrocephalus with headaches and papillœdema In most cases of lateral sinus thrombosis however the clot is infected and manifestations of pyæmia rapidly ensue Meanwhile the clot may extend into the jugular vein and cause pain and stiffness in the side of the neck and occasionally the thrombosed jugular vein may be felt beneath the anterior border of the sterno mastoid as a tender solid cord There may be tenderness and swelling over the region of the mastoid emissary vein and the cervical lymph glands may be enlarged If when Queckenstedt s test is performed the jugular veins are compressed separately compression of the vein on the side of the obstructed sinus causes little or no rise in the manometer whereas compression of the other gives a normal result

Cavernous sinus—Thrombosis of this sinus is usually consequent upon septic spots or injuries on the face sepsis in the frontal sinus or orbital cellulitis Ordinarily the thrombus is infected There is œdema of the orbit with proptosis and œdema of the conjunctiva forehead and face Amblyopia or blindness is the rule but the appearance of the fundus of the eye usually remains normal until the late stages Paralysis of the ocular muscles and anæsthesia of the eye may also occur The condition usually becomes bilateral within a day or two

Diagnosis—This usually depends on the presence of some of the conditions with which sinus or venous thrombosis is known to be associated The possibility of clot in the superior longitudinal sinus and related veins should always be considered (1) *when any convulsive or paralytic phenomena comes on within a month* of childbirth or abortion (2) when in an elderly or debilitated patient manifestations which may include alexia and visual disorientation suggesting vascular lesions on

the two sides of the brain occur within a few days of each other (3) when signs of hydrocephalus appear in association with or soon after an attack of otitis media, and there are no other indications of cerebral abscess and (4) when paralytic or convulsive phenomena occur soon after an injury near the vertex of the skull

Lateral sinus thrombosis is almost exclusively associated with ear disease and its presence can usually be confirmed by Queckenstedt s test Thrombosis of the cavernous sinus presents such a characteristic picture that if an exciting cause is present the diagnosis is seldom in doubt

Prognosis —In the non infective cases the prognosis as regards life is usually good The paralytic phenomena generally make great and often complete recovery within a few weeks but in the severe cases spasticity in the legs and upper arms may be left Blindness or impairment of vision may follow cavernous sinus thrombosis As to the infected cases the prognosis formerly ominous has been greatly improved by the introduction of the sulphonamide drugs and penicillin With lateral sinus thrombosis recovery usually follows prompt operation

Treatment —In the non infective cases the first indication is to allay convulsions if present and doses of soluble phenobarbitone up to gr 3 at a time may be administered by intramuscular injection or by mouth if that is possible Anticoagulants may be employed to prevent the spread of thrombosis but they should be used with full knowledge of the risk of toxic effects (see p 847) For the paralytic phenomena the treatment is identical with that of cases of cerebral arterial thrombosis

The infective cases should be treated immediately as cases of septicæmia and if the local exciting conditions are likely to involve any collection of pus such as an epidural abscess appropriate prompt surgical measures should be taken

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

Before the War of 1914–1918 syphilis was responsible for far more cases of organic nervous disease than any other single factor but during the last 40 years the incidence of neurosyphilis in the United Kingdom has shown a steady decline until it is now less than a tenth of what it formerly was

It is known that in many cases of syphilis the meninges become infected with the syphilitic organism early in the secondary stage but in most cases especially if adequately treated this infection dies out within a year or two In a number of patients however it persists and may become very resistant to treatment After an interval which is seldom less than 2 years syphilitic disease of the meninges and of the blood vessels of the central nervous system may give rise to symptoms and in other instances after an interval varying between 5 and 30 years disease of the cerebral parenchyma may become manifest as general paralysis of the insane or degeneration of fibres in the posterior nerve roots and spinal cord may give rise to tabes dorsalis

In meningeal and vascular syphilis the lesions are composed of miliary gummata They commence with the collection of spirochætes in the spaces surrounding the small arteries and this is followed by an inflammatory reaction with œdema and the exudation of many lymphocytes and plasma cells around the small vessels These cells may wander freely into the nervous tissues away from the vessels and may form clumps often containing giant cells and these too are miliary gummata The initial periarteriolar inflammation is followed in many instances by invasion of the whole vessel wall (panarteritis) and often the most conspicuous feature in such panarteritis is a proliferative endarteritis which may give rise to thrombosis

The sequence of events in the primary degenerative processes in parenchymatous

syphilis is less well known and these processes are as yet unexplained In only one form of nervous syphilis namely general paralysis of the insane is *Treponema pallidum* found in the parenchymatous elements of the central nervous system

In cases of neurosyphilis the Wassermann reaction is usually positive in the blood The most frequent exceptions to this are in cases of tabes dorsalis in which disease the blood Wassermann reaction is negative in about 30 per cent of cases

The cerebrospinal fluid in neurosyphilis shows typically a group of changes, comprising lymphocytosis excess of albumin and a positive Wassermann reaction The Wassermann reaction may however be negative in the fluid when it is strongly positive in the blood and this combination is commonly met with in cerebral meningo-vascular syphilis It is thus essential in all cases in which syphilis is a possible cause of central nervous symptoms to examine the Wassermann reaction both in the cerebro spinal fluid and in the blood, since either may give a positive result when the other is negative In some cases of neurosyphilis particularly tabes the cerebrospinal fluid is normal in every way

GENERAL PARALYSIS OF THE INSANE

Synonym —Dementia Paralytica General Paresis

Definition —This is a progressive disease of the brain due to syphilis causing mental and physical deterioration and finally dementia and paralysis

Ætiology —Infection with *Treponema pallidum* (*Spirochæta pallida*) is the essen tial cause and the disease usually begins between 8 and 20 years after infection The incidence is much greater among males than among females and the onset of the disease occurs most often between the ages of 30 and 50 It may appear in adolescence as the result of congenital infection The incidence among syphilitics in general has been estimated as high as 5 per cent but among those who have been well treated in the early stages the incidence is probably less than 1 per cent It formerly represented about 10 per cent of all cases of neurosyphilis and nearly a quarter of those treated as hospital in patients

Pathology —At necropsy the brain appears atrophic the sulci being widened and the convolutions reduced in size These changes are most pronounced over the anterior and middle portions of the hemispheres but in some cases only the occipital poles escape The meninges often show considerable thickening and opacity and the pia adheres firmly to the cortex On section the cortex is found to be reduced in thickness The ventricles are enlarged as a result of the atrophy of the brain substance and their ependymal lining appears granular or frosted

The essential changes are in the ganglion cells of the cerebral cortex. Micro scopical examination under the low power shows that many of these cells have dis-appeared and that those remaining are arranged irregularly The cells are often shrunken and their nuclei stain deeply In association with the neuronic damage there is a marked reaction of the glial cells and histiocytes (rod cells) The subpial lamina of glial tissue is increased The histiocytes proliferate and hypertrophy and when stained with Prussian blue are found to contain iron in their cytoplasm—a pathognomonic finding Many of the cortical blood vessels are surrounded by a peri vascular cuff of lymphocytes and plasma cells and the vessels often show prolifera tive changes in their endothelium

Treponema pallidum can be demonstrated in the nervous tissue

Symptoms —For months before intellectual defect becomes apparent the patient has usually shown some defect of emotional control He has become excitable moody liable to outbursts of temper and easily moved to tears by music or the cinema Thereafter he begins to show a lack of concentration and persistence he ceases to pursue his old interests and adopts new ones in rather rapid succession At this

the two sides of the brain occur within a few days of each other (3) when signs of hydrocephalus appear in association with or soon after an attack of *otitis media* and there are no other indications of cerebral abscess and (4) when paralytic or convulsive phenomena occur soon after an injury near the vertex of the skull

Lateral sinus thrombosis is almost exclusively associated with ear disease and its presence can usually be confirmed by Queckenstedt s test Thrombosis of the cavernous sinus presents such a characteristic picture that if an exciting cause is present the diagnosis is seldom in doubt

Prognosis —In the non infective cases the prognosis as regards life is usually good The paralytic phenomena generally make great and often complete recovery within a few weeks but in the severe cases spasticity in the legs and upper arms may be left Blindness or impairment of vision may follow cavernous sinus thrombosis As to the infected cases the prognosis formerly ominous has been greatly improved by the introduction of the sulphonamide drugs and penicillin With lateral sinus thrombosis recovery usually follows prompt operation

Treatment —In the non infective cases the first indication is to allay convulsions if present and doses of soluble phenobarbitone up to gr 3 at a time may be administered by intramuscular injection or by mouth if that is possible Anticoagulants may be employed to prevent the spread of thrombosis, but they should be used with full knowledge of the risk of toxic effects (see p 847) For the paralytic phenomena the treatment is identical with that of cases of cerebral arterial thrombosis

The infective cases should be treated immediately as cases of septicæmia and if the local exciting conditions are likely to involve any collection of pus such as an epidural abscess appropriate prompt surgical measures should be taken

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

Before the War of 1914–1918 syphilis was responsible for far more cases of organic nervous disease than any other single factor but during the last 40 years the incidence of neurosyphilis in the United Kingdom has shown a steady decline until it is now less than a tenth of what it formerly was

It is known that in many cases of syphilis the meninges become infected with the syphilitic organism early in the secondary stage but in most cases especially if adequately treated this infection dies out within a year or two In a number of patients however it persists and may become very resistant to treatment After an interval which is seldom less than 2 years syphilitic disease of the meninges and of the blood vessels of the central nervous system may give rise to symptoms and in other instances after an interval varying between 5 and 30 years disease of the cerebral parenchyma may become manifest as general paralysis of the insane or degeneration of fibres in the posterior nerve roots and spinal cord may give rise to tabes dorsalis

In meningeal and vascular syphilis the lesions are composed of miliary gummata They commence with the collection of spirochætes in the spaces surrounding the small arteries and this is followed by an inflammatory reaction with œdema and the exudation of many lymphocytes and plasma cells around the small vessels These cells may wander freely into the nervous tissues away from the vessels and may form clumps often containing giant cells and these too are miliary gummata The initial periarteriolar inflammation is followed in many instances by invasion of the whole vessel wall (panarteritis) and often the most conspicuous feature in such panarteritis is a proliferative endarteritis which may give rise to thrombosis

The sequence of events in the primary degenerative processes in parenchymatous

coma following a fit In some cases convulsions are the first manifestation to attract attention When the patient is examined however it is usually found that he is already tremulous Such cases are among the most favourable for treatment, because the disease may be arrested before mental deterioration has become apparent Insomnia is frequent in the prodromal period but in the early stages sleep is often excessive Later sleeplessness and motor restlessness are often troublesome symptoms

Tabo paresis.—The condition known as tabo paresis consists of a combination of certain features of general paralysis with certain features of tabes The mental symptoms are as a rule relatively mild tremor and the speech disturbances are moderate, the knee jerks and ankle jerks are absent and there is usually some sensory impairment of tabetic type and distribution the pupil reactions are likely to be of the Argyll Robertson type and optic atrophy may be present A considerable number of cases of nervous syphilis in which optic atrophy is the first recognised feature develop as cases of tabo paresis

SEROLOGICAL REACTIONS —Provided the patient has not recently received antisyphilitic treatment his blood will almost certainly give a positive Wassermann reaction A negative result however should not be accepted as conclusive evidence against the presence of general paralysis of the insane The cerebrospinal fluid in an untreated case usually shows an increase in the number of white cells and in the protein content, with excess of globulin, the Wassermann reaction is invariably strongly positive and Lange s colloidal gold test almost always shows maximal changes in the first four or five tubes (paretic type of curve)

Diagnosis —The diagnosis depends on the combination of mental changes with typical changes in the cerebrospinal fluid Tremor is almost invariably present at any rate in the voice In the complete absence of tremor even when the fluid changes are typical it may be doubted whether the condition present is general paralysis of the insane and not one of the other forms of cerebral syphilitic disease Cerebral meningo vascular syphilis may cause mental deterioration and paralysis but tremor is seldom prominent and the changes in the cerebrospinal fluid especially the colloidal gold reaction are likely to be somewhat less intense

In the absence of reliable examination of the cerebrospinal fluid or blood the history of change in the patient s character combined with intellectual deterioration impaired emotional control and tremor is almost sufficient for the diagnosis Commonly the patient himself has little or no insight into his altered state and may express his subjective sense of well being and of intellectual acuity in glowing terms that arouse a suspicion of the true state of affairs in the trained observer The non syphilitic conditions which cause a similar gradual change are rare with the exception of arteriosclerotic dementia The latter usually occurs at a later age than general paralysis and is associated with less tremor In general paralysis pupillary abnormalities are almost constant and slurring articulation soon becomes added to the tremor of the voice

In rare cases chronic alcoholism gives rise to an expansive mental state and tremulousness which cannot with confidence be distinguished from general paralysis without examination of the cerebrospinal fluid With delirium tremens visual hallucinations are a prominent symptom Alzheimer s disease is a rare form of degeneration of the frontal lobes which comes on in middle age and causes gradual mental deterioration associated with tremor Pupillary abnormalities are absent (see p 1630) In the absence of pupillary or other clinical signs of nervous syphilis it may be impossible to distinguish the depressed form of general paralysis of the insane from other states of depression In many cases the tremulousness may suggest the correct diagnosis but some tremor may also be seen in cases of depression with agitation due to other psychoses When a history cannot be obtained and the patient is in a maniacal or a hypomanic state the differentiation from other forms of mania may for a time be impossible

stage he is 'full of ideas' but soon begins to show deficiency of judgment in applying them seeing only the great advantages of his schemes and forgetting his own limitations He assumes his ability to attain every wish, and this may lead to outbursts of wild extravagance By this time he has become forgetful, inattentive to business and careless Within a short time he has actual delusions concerning his own capacity, and he may boast of his physical power, wealth or social position but the classical delusions of grandeur are now a rarity

In many other cases the symptoms are merely those of simple dementia with gradual reduction of interests and of mental and physical activity The patient's ability to perform his usual work is gradually impaired, especially if it is of a mental character, and when calculation is involved his mistakes become frequent In a large number of such cases the patients are depressed in the early stages and the subsequent *delusions may be melancholic or hypochondriacal As the disease progresses,* memory becomes more and more defective excitability and activity give way to apathy and lethargy and delusions die out The patient lies in his bed showing little sign of mental activity indifferent to his surroundings incontinent and more or less paralysed

The first of the physical changes accompanying the mental deterioration is almost always tremor Usually if not always it begins by affecting the voice giving it a vibrant emotional quality but this change usually escapes notice When however the tongue lips and cheeks become tremulous the irregularity of articulation is pronounced The typical tongue tremor is a backward and forward 'trombone' movement of the organ when the attempt is made to protrude it Speech is often affected early At first it is merely hesitant later it becomes indistinct and irregular, syllables are omitted interpolated or slurred and the voice becomes feeble and lacks intonation Utterance then becomes jerky, and consonants are slurred Changes at a higher physiological level in the speech system also occur and cause elision of syllables or of words, and attacks of aphasia are not uncommon As the memory fails confusion arises in the construction of long sentences proper names are forgotten the choice of *adjectives and verbs becomes more and more limited and the* vocabulary diminishes until only interjections are left Written language suffers in the same way and may show defects of execution and of ideation before spoken speech is noticeably altered Tremor becomes marked in the hands and other parts of the body and because of the unsteadiness of the hand the writing deteriorates and with the intellectual deterioration words are often misspelt

Apart from tremor there are no physical signs that can be counted upon in the early stages Pupillary abnormalities are very common but they simply indicate central nervous syphilis and have probably been present for some time before the onset of general paralysis The complete Argyll Robertson phenomenon is not very common but incomplete forms of it and inequality and irregularity of the pupils are usual Signs of disturbance of the pyramidal system—extensor plantar reflexes and exaggeration of the tendon jerks—usually occur before long If any of the tendon jerks are absent as is not uncommon *it is because of the presence of an element* of tabes dorsalis Incontinence of urine often occurs early but it is more often due to lack of attention than to any failure of the sphincter reflexes At a later stage control of both bladder and rectum is always lost. Sexual impotence is present in most cases for several years before mental symptoms appear but in a few of the more acute cases the onset is accompanied or preceded by a phase of sexual excitement

As the disease advances the paralytic features become more pronounced In the so called congestive attacks hemiplegia or monoplegia appears with or without an initial Jacksonian fit Recovery occurs in the course of a few days or weeks but the limbs gradually become weak

Generalised epileptiform seizures are common and often aggravate the pre existing symptoms and in a large proportion of cases death eventually occurs in

more easily controlled methods of producing it were developed, the most successful of which was the heating of the body in a suitable cabinet by electrical short waves

After any successful treatment clinical improvement is very gradual The first clinical effects are the reduction of tremor and of excitability and an improvement in the patient s memory and alertness During the next few months improvement in favourable cases is pronounced but 2 years elapse before the full effect is obtained Changes in the cerebrospinal fluid with one important exception are equally gradual Within a few weeks of the end of successful treatment the number of cells in the cerebrospinal fluid falls to near the normal level (3 per c mm) indicating the cessation of active inflammation in the central nervous system but the other abnormalities in the fluid show for the time being little change The Wassermann reaction of the fluid usually dies out in the course of a year or so but the paretic colloidal gold curve may persist for several years and its presence is not to be regarded as a sign of syphilitic activity If treatment has not been successful in eradicating the infection the first sign of relapse is an increase in the number of cells in the cerebrospinal fluid and such increase will almost invariably be observable by the end of 6 months consequently, if at the end of 6 months the cerebrospinal fluid contains more than four cells per c mm a further course of treatment should be given

The effect of modern therapy is to arrest the active disease and the clinical results depend chiefly on the degree of mental deterioration that had occurred before treatment was instituted The most satisfactory cases are those in which convulsions or other acute phenomena have brought the patient under care before mental impairment has become obvious However, patients with mental symptoms of short duration often do well In cases of slower evolution with evident mental impairment arrest of the disease may leave the patient incapable of useful mental work and unfit to hold any position of responsibility

In occasional cases cerebral degenerative changes of a non specific character occur in later life and give rise to a secondary dementia

CEREBRAL SYPHILIS

Synonym —Cerebral Meningo Vascular Syphilis

Definition —In most of the cases to which the term cerebral syphilis is applied the chief incidence of the syphilitic process is upon the meninges and blood vessels the brain being affected in a less degree and by secondary processes Actual syphilis of the brain is uncommon It occurs however in two forms (1) Gumma of the brain and (2) a diffuse gummatous infiltration throughout the cerebral hemispheres or even in the cerebellum the meninges always being involved to some extent

Ætiology —Cerebral syphilis (as distinct from general paralysis of the insane) occurs in about 4 per cent of all persons who acquire syphilis The onset of symptoms is commonest from 1 to 5 years after infection but it may be as early as 2 or 3 months or as late as 30 or 40 years Characteristically the patients are young men but a stroke due to syphilitic vascular disease may occur at any age and at any interval after infection

Pathology —Both the meninges and the cerebral blood vessels are always affected but the degree of involvement of each is subject to great variation When the disease falls chiefly upon the meninges it most frequently causes a diffuse subacute or chronic gummatous leptomeningitis at the base of the brain Less often it affects the coverings over the convex surface of the brain and if so it is usually more intense over the frontal and parietal lobes than over the occipital and temporal —In severe cases a gelatinous exudate fills the subarachnoid space and extends along the vessels and nerves Later the newly formed tissue organises and forms sclerosed gummata Hydrocephalus

Course and Prognosis—The onset is usually insidious The disease may then progress steadily or in the early stages show exacerbations with maniacal outbursts In the absence of effective treatment death usually occurs within 3 years and in a large proportion of cases the duration is about 1 year If convulsions are frequent the termination is likely to occur sooner and acute cases may run their course in a few weeks Usually the disease is less acute in women than in men

The duration of tabo paresis is generally a good deal longer than that of general paralysis and in cases due to congenital infection the course is often prolonged

Treatment—PROPHYLACTIC—The eventual occurrence of general paralysis of the insane may be feared in any case in which 2 years or more after infection the lymphocytosis in the cerebrospinal fluid is resistant to courses of antisyphilitic treatment Preventive treatment then consists in a course of penicillin injections as in the curative treatment of general paralysis If the interval from the time of infection is as long as 5 years and the colloidal gold curve is of the paretic type, such preventive treatment should not be delayed

CURATIVE—It is important that the physician in charge of a case of general paralysis should have clearly in mind both the possibilities and the limitations of treatment Cure consists of two distinct parts—the eradication of the syphilitic infection from the brain, and the restoration of normal cerebral function The means of treatment at our present disposal may accomplish the former and do not aim beyond that The subsequent restoration of cerebral function depends on the recovery of such cerebral tissue as is capable of recovery and we have as yet no means of influencing the natural course of this process This recovery continues over a period of about 2 years and attains very different degrees according to the amount of damage already suffered by the brain before the disease was arrested the acuteness or chronicity of the inflammation and other factors While the corresponding mental recovery reaches a gratifying level in many patients in whom the disease is recognised and treatment begun reasonably early there are many others in whom it is never sufficient to restore the patient to a position of social usefulness

For the eradication of the syphilitic infection from the brain penicillin now provides the method of choice As however this treatment is relatively new some physicians still prefer to re enforce it with a (shortened) course of pyrexial therapy The penicillin treatment consists of the administration of a minimum of 5 million Oxford units intramuscularly over a period of approximately 10 days and it is now usual to give about 10 million units in a single course or in two courses Having begun with injections of 15 000 units or so three times in the course of the first day it is usual to proceed with doses of the order of 60 000 units every 3 hours until a total of 5 or 6 million units has been attained i e 10 or 12 days more Various methods of maintaining the concentration of penicillin in the blood with less frequent injections, e g one every 24 hours are on trial but none has yet obtained general acceptance No penicillin is given intrathecally During the course of penicillin therapy a mixture containing iodide of potassium (gr 20 or gr 30 to the dose) and mercuric chloride solution (1 in 1000) (½ to 1 drachm in each dose) should be given by mouth with the idea of aiding the absorption of gummatous elements in the brain and meninges

It was discovered in 1917 that general paralysis could be arrested by malaria and for the next 30 years benign tertian malaria was used all over the world as a therapeutic measure The patient was allowed to have from 6 to 12 rigors according to his physical state and then the malaria was stopped by quinine or mepacrine The treatment was mostly carried out in special hospitals or clinics with expert medical nursing staff and under such conditions the mortality (from the disease and from the malaria) during the stage of active treatment was of the order of 10 per cent but under less favourable conditions it was much higher

When it was established that the pyrexia was the actual curative agent various

Fluctuation in the symptoms is one of the features of the disease and in the milder cases the patients may be well for months at a time

Prognosis —With antisyphilitic treatment a large measure of recovery is the rule but some mental impairment headaches and occasional fits are common residual phenomena Signs of hydrocephalus may persist in some degree Hemiplegia may respond to antisyphilitic treatment but in the majority of cases it is little affected

Treatment —Prophylactic —If syphilis has been contracted it should be thoroughly treated in its early stages When the Wassermann reaction of the blood has been rendered negative the test should be repeated once a year for the first 5 years and then every 2 years The cerebrospinal fluid should be examined after the blood has been rendered negative but an interval of 2 or 3 months should be allowed between the end of a course of treatment and the lumbar puncture If the cerebrospinal fluid then gives a positive reaction treatment should be continued and the fluid should be examined as before 3 months after the end of the course of treatment

Curative —As soon as the diagnosis is made and in very acute cases even before it is established antisyphilitic treatment should be begun with potassium iodide and mercury by the mouth and within a day or two a course of penicillin as described for general paralysis of the insane (p 1458) should be started The potassium iodide and mercury can be combined in the following mixture potassium iodide gr 10 to 20 solution of mercuric chloride mins 30 to 60 arsenical solution mins 2½ chloroform water fl oz ½ This should be taken with as much water as desired three times a day after food but is not to be taken when the stomach is empty If either dyspepsia or diarrhœa occurs the mixture should be stopped for a time and replaced by one containing bismuth carbonate gr 15 instead of the solution of mercuric chloride

ACUTE SYPHILITIC MENINGITIS

This is a rare condition almost confined to young men It occurs usually within a year or two of infection and has even been associated with the secondary rash A peculiar feature is that acute syphilitic meningitis or a condition closely resembling it (meningo recidive aigu) may occur during a course of arsenical injections and there is some reason to believe that in such instances the treatment is a precipitating factor

Symptoms —The clinical picture is indistinguishable from that of other kinds of acute meningitis Headache is intense the temperature may rise to 102 or 103 F the patient is delirious and may have maniacal outbursts and stiffness of the neck is present but Kernig s sign is not usually pronounced The optic disks may be blurred and slightly swollen The condition of the pupils is not usually of diagnostic value The tendon and plantar reflexes are variable as in other kinds of acute meningitis The cerebrospinal fluid may contain 1000 or 1500 cells per cubic millimetre of which as many as 30 per cent or even more may be polymorphonuclear The Wassermann reaction is strongly positive both in the cerebrospinal fluid and in the blood

Treatment —With the administration of potassium iodide and mercury by the mouth and the injection of small doses (10 000 to 15 000 units) of penicillin intramuscularly at 6 hourly intervals the fever and delirium quickly subside and the headache abates Treatment must then be pursued on the same lines as for other forms of meningo vascular syphilis Good recovery is the rule but some mental impairment is often left

TABES DORSALIS

Synonym —Locomotor Ataxia

Definition —This is a disease of syphilitic origin characterised clinically by ataxia

may result Many symptoms of cerebral syphilis are caused indirectly and result from hydrocephalus or vascular disturbances In rare instances syphilitic infection gives rise to an acute diffuse meningitis indistinguishable without special tests from other kinds of acute meningitis (see p 1461)

In cases where the main incidence falls upon the blood vessels the arteries at the base of the brain forming the circle of Willis or arising from it, together with their branches are most often attacked To the naked eye they show irregularities in size, due to thickening of their walls in circumscribed areas Proliferation of the intima, together with a round celled infiltration of the outer coats—endarteritis obliterans—is the characteristic microscopical change In smaller arteries within the brain or on its surface the same changes occur and these vessels as well as those at the base may be compressed or invaded by disease beginning in the meninges In each case their lumen is narrowed or obliterated thrombosis occurs readily and softening results in parts from which the blood supply is cut off Obliterative changes also occur in the veins and perivascular spaces and lead to further impairment of the nutrition of the brain

Gumma of the brain is rare When present it arises from the meninges and may be multiple and the convexity of the hemisphere in the motor region is the site of election A gumma may spread so as to involve the overlying bone

Symptoms —The symptoms of basal meningitis are partly general and partly local from involvement of some of the cranial nerves The general symptoms are headache, lethargy and impairment of intellect and memory The headache is deep seated and severe The lethargy is variable and may pass off for a time or may deepen into stupor Any one or several of the cranial nerves may be paralysed Ocular symptoms are rarely absent pupillary changes being the rule and external ocular palsies common Mild papillœdema is also common and optic atrophy may occur in one or both eyes A symptom presumably due to involvement of the hypothalamus or of the pituitary is obesity Diabetes insipidus sometimes occurs

When the meningitis is distributed chiefly over the convexity of the cerebral hemispheres there may be long periods of intermittent headache which is acute and usually situated near the vertex of the skull and the skull may be tender In severe cases convulsions are common they are most frequently generalised epileptiform fits but Jacksonian attacks are not uncommon and are usual in the more chronic cases Attacks of aphasia may occur In all the more severe cases some mental impairment is the rule usually simple dementia but there may be mild delusions and emotional instability is common

When the blood vessels are predominantly affected premonitory symptoms often occur before there is any severe stroke These consist of transitory weakness of one arm or other part of the body or of local twitching Headaches are common Hemiplegia is the usual syndrome which supervenes and in some of these cases it is of the most severe type In addition to the paralysis and spasticity there may be sensory loss in the affected limbs and complete or partial hemianopia Aphasia usually accompanies right sided hemiplegia The Wassermann reaction is usually strongly positive in the blood

Diagnosis —This depends largely on the discovery of a positive Wassermann reaction It is usually positive in the blood but in many cases it is negative in the cerebrospinal fluid Pupillary abnormalities may be of great help in suggesting syphilis as a cause but the possibility of a tumour in the mid brain must be borne in mind The Argyll Robertson pupil in its pure form is not common in cerebral meningo vascular syphilis

Jacksonian epilepsy or fits of any kind in patients—particularly male patients between 21 and 25—are suggestive of syphilitic meningitis or gumma even though these are not now the commonest cause of such symptoms This applies particularly if the attacks are of a peculiar character such as an attack of automatism and amnesia

several years' duration In other cases the patient mentions his pains but their significance escapes notice because it is thought that they are too slight to be tabetic pains It must be made clear at once therefore that the peculiarity of the pains in tabes does not lie in their severity for they vary from a trifling sensation of discomfort to almost intolerable agony, but in their distribution, in their direction of propagation, and especially in their arrangement in time

As a rule they come on in attacks in which single momentary pains are repeated at intervals of a few seconds or minutes for several hours the whole bout lasting several days or weeks Between the attacks there may be long intervals of complete freedom from pain The pains are felt most often in the lower limbs but any part may be affected They may be referred to the skin to the muscles or to the bones They are very common in the bony prominences around the knee and on the foot. The direction of radiation varies In some the pain seems to shoot up or down a limb but in a larger number it seems to strike the limb vertically, as if a sharp object were piercing it from without. Some patients experience both kinds of pains The onset of each pain is always sudden If it is severe the patient may cry out and if it overtakes him whilst walking he is forced to stop The duration of each pain is usually momentary, but sometimes it lasts a second or two and fades away gradually

Other pains with characters which are not peculiar to tabes are common They are described as aching burning or gnawing pains Like the lightning pains they alter with changes in the weather and are usually attributed to rheumatism Other common subjective sensory symptoms are pins and needles in the extremities a feeling of walking on a soft substance and of constriction around the trunk or limbs. More important than these because it often appears very early is hyperæsthesia of the trunk, especially in its lower part Light touches or applications of water at certain temperatures are almost unbearable In cervical tabes sensory disturbances occur first in and are more severe in the arms

Objective—In association with the foregoing subjective disturbances objective impairment of pain appreciation develops For some unknown reason this impairment (hypalgesia) has a strongly selective incidence the areas at first affected being as follows (i) a band across the chest, (ii) over the lower halves of the shins (iii) on the nose and (iv) on the ulnar borders of the forearms As the disease advances the areas thus affected extend and eventually pain appreciation may be impaired over the whole surface of the body Deep pain appreciation becomes similarly affected

REFLEXES —Simultaneously with the involvement of the pain fibres, or very soon afterwards the fibres which subserve reflex activities are affected with consequent gradual interruption of the reflex arcs The ankle-jerks and knee-jerks disappear. Loss of the ankle-jerks is an early sign in tabes, and often precedes loss of the knee jerks by many years The tendon reflexes in the upper limbs are lost early in cervical tabes and are frequently absent in cases of the ordinary type The triceps-jerk is usually the first to go. The skin-reflexes are often exaggerated to a degree rarely met with in other diseases This is best seen on the abdomen and is usually associated with hyperæsthesia to touch and temperature The plantar reflex is usually normal It is sometimes absent when sensory loss on the soles is severe and in cases where sclerosis of the pyramidal tract exists as a complication of tabes the response is extensor

HYPOTONIA —Muscle tone which is a reflex function gradually becomes affected too and in any established case passive movement of the lower limbs reveals definite hypotonia The decrease in the tone of the muscles is often well marked at a time when lightning pains are the only symptom of tabes and loss of skin sensation the only other manifestation It is shown by flaccidity of the muscles, and by an abnormal range of active and passive movement of the limbs. The leg can often be raised to an angle of 100 from the horizontal with the knee extended whereas a normal

of the lower limbs in walking and by numerous other signs and pathologically by degeneration of the posterior columns of the spinal cord

Ætiology —Syphilis is the essential factor in causation Little is known of the contributory factors which determine the occurrence of tabes dorsalis in some persons with syphilis and not in others Males are affected a good deal more frequently than females The onset is usually between the ages of 30 and 45 years and usually between 5 and 15 years after infection It may occur in both husband and wife—"conjugal tabes" It also occurs not very rarely as a result of congenital syphilis and then appears in adolescence or early adult life

Tabes dorsalis was once the commonest form of neurosyphilis but its frequence has shown a marked decline in recent years

Pathology —The most evident morbid change is degeneration in the posterior columns of the spinal cord It is however generally believed that this is not primary but results from disease affecting the fibres of which these columns are composed before they enter the cord These fibres and other fibres of the posterior spinal roots are most probably affected by syphilitic toxins either where the nerves pass through the meninges or where the roots enter the spinal cord As a secondary change the neuroglia around the degenerated fibres increases in amount and density Hence the characteristic feature in sections of the cord in tabes is shrinkage and sclerosis of the posterior columns The sclerosis usually appears earliest in the postero lateral columns of the lower lumbar and upper sacral regions but in advanced cases when the dorsal and cervical sensory roots are also affected the posterior columns are sclerosed through out In advanced cases the endogenous tracts of the posterior columns show degeneration, and in some the afferent tracts in the lateral columns are also affected In addition there is often a subpial or marginal degeneration practically all round the cord at many levels

Atrophy of the optic nerves commonly occurs and seems to be the result of a combined interstitial gummatous inflammation and primary degeneration of the nerve fibres The ocular palsies of tabes are probably mainly due to gummatous meningitis but there may be a degeneration of the nerve cells in the nucleus of the third nerve

Symptoms —Few diseases cause so many different symptoms The most common features are (i) lightning pains , (ii) objective disturbances of sensation (iii) loss of tendon reflexes (iv) ataxia (v) disturbance of pupillary reflexes especially the Argyll Robertson pupil and (vi) impairment of bladder control Less frequent are (vii) visceral crises', *i e* acute disturbances of function of certain viscera of which gastric crises are the most common but rectal vesical and laryngeal crises also occur (viii) atrophy of the optic nerves (ix) trophic changes—(*a*) Charcot s disease of joints (*b*) perforating ulcers of the skin and (*c*) a general trophic effect which renders the patients thin

The usual syndrome is essentially that of degeneration of the posterior spinal nerve roots, or of the corresponding nerve cells in the posterior root ganglia and, in fact of the afferent elements of the nervous system in many parts of the body

SENSORY DISTURBANCES —*Subjective* —Lightning pains are usually the first symptom—sudden intense stabbing pains which seem to shoot into parts of the lower limbs They occur at irregular intervals and usually in bouts vary greatly in severity, and are often mistaken for rheumatism or neuritis These pains merit the closest attention They are rarely absent they often precede other symptoms by 5 or 10 or more years and most important of all they possess peculiar features which render them pathognomonic of tabes and allow the diagnosis to be made in a syphilitic subject on their presence alone Although they are rarely absent careful interrogation may be needed to disclose them To the question Have you any pains ? the patient may answer No If then he is asked if he has rheumatism he will often answer Yes and proceed to give an account of characteristic tabetic pains of

comes on at a later stage and it is compensated for by elevation of the eyebrows In addition there are a general flabbiness of the facial musculature and a greyish pallor of the skin All these features combine to give the patient a somewhat distinctive facial appearance—the tabetic facies

Optic atrophy.—Syphilitic optic atrophy is an important complication and occurs with such frequency that it is often called tabetic optic atrophy It has been estimated that it is found in about one case in ten It may be the first indication of neuro syphilis The peripheral portion of the visual field is lost first, and charts of the fields at this stage have a most irregular outline Central vision is the last to fail and as long as it persists the impairment of sight may escape notice The most acute cases proceed to complete blindness in 2 months but the slow cases take many years or remain unilateral The atrophy is primary, that is it is not preceded by papill œdema The disk becomes white and flat, and is sharply outlined. Cases of tabes which begin with optic atrophy do not, as a rule, develop much ataxia, but they often develop mental disturbances and become cases of tabo-paresis

VISCERAL CRISES —Occasionally attacks of intractable vomiting occur each lasting a few days and during this time the patient cannot keep anything down The vomiting may be associated with epigastric pain but more often there is merely discomfort. Tabetic pains in the back are commonly associated with or precede the crisis When the attack is over the patient is quickly well again, but such attacks continue to occur at intervals of months or weeks They often take place before other symptoms of tabes dorsalis have attracted attention, and the vomiting is not infrequently attributed to intestinal obstruction or to perforation of the stomach with the result that laparotomy is performed Rectal crises consist of painful and prolonged tenesmus, vesical crises of severe dysuria and laryngeal crises of prolonged spasm of the larynx causing stridor cough and dyspnœa

TROPHIC CHANGES —*Charcot s disease of joints*—In some cases, usually those of a very chronic type severe disease leading eventually to articular disorganisation occurs in one or two joints The first sign is usually rapid swelling in and around a joint, with effusion and œdema The effusion in slight cases subsides slowly and the joint recovers but more often the enlargement is followed by destruction of the cartilages wasting of the ends of the bones periarticular new bone formation and destruction of the ligaments The joint becomes disorganised, the range of movement is increased and crepitations of startling coarseness are heard and felt when the part is handled The characteristic feature is the complete absence of pain Dislocations occur readily especially at the hip and the presence of an arthropathy may be first revealed by the occurrence of a pathological fracture of the neck of the femur The diseased joint sometimes becomes infected most frequently in the foot The joints most often attacked and in order of frequency are knee hip ankle, small joints of the hands and feet the spine shoulder and elbow

Charcot s disease of joints is very frequently associated with negative Wassermann reactions both in the blood and the cerebrospinal fluid In one instance in which the blood and cerebrospinal fluid gave negative results fluid aspirated from the affected joint gave a strongly positive reaction

In certain tabetic patients changes occur in some of the bones so that they break with a small degree of violence

Perforating ulcers of the skin—Trophic changes in the skin give rise to chronic ulcers, usually on the sole of the foot which gradually increase in depth until the foot may be perforated These ulcers like the other trophic disturbances of tabes are usually painless

Tabetics tend to get thin and a slow loss of weight is an early sign If there is any tendency for the weight to increase a paretic element is almost certainly present. Manifestations of syphilis in other organs are rare in the course of the disease with the exception of aortitis, which occasionally occurs

person cannot raise it more than 60°, and excessive range of *dorsiflexion of the foot* is often a striking sign In extreme cases the legs can be made to encircle the neck the body can be flexed so that the head touches the bed between the knees and the patient is able to imitate the tricks of the double jointed man

ATAXIA —At a slightly later stage the coarser fibres in the posterior roots which are concerned with sense of position suffer in the same way as the pain and reflex fibres The patient then becomes unable to appreciate exactly the position of his extremities As a rule the lower limbs are affected first and most The patient becomes unable to direct the movements of his feet exactly and fails to maintain his centre of gravity in the right position relative to them with the result that he becomes unsteady The trouble is first noticed when co ordinated movements have to be performed without the aid of vision, as when the patient is washing his face in the morning This disability is partly overcome for a time by separating the feet so that the patient stands and walks on a wide base, he watches the ground and is much more unsteady with his eyes closed or in the dark When standing with his feet together he is more unsteady with his eyes closed than with his eyes open (Romberg's sign) As the loss of sense of position advances and at the same time the controlling influence of muscle tone is lost movements of the lower limbs become very irregular In walking the feet are raised too high and are brought down with irregular force often too violently so that the gait becomes stamping The steps are of irregular length The patient staggers from side to side and may fall Eventually walking may become impossible The same inco ordination of movement occurs in the upper limbs but usually in less degree The patient becomes unable to direct the movement of his hands and fingers exactly without watching them later he becomes clumsy and eventually may become unable to feed himself

SPHINCTER TROUBLES —These are the result of lowering of pain sensibility in the bladder which is the afferent element in the reflex of micturition An increased distension of the bladder becomes essential before the act can be started and this fails before the bladder is completely emptied and residual urine is present in slowly increasing quantity Though this causes little or no inconvenience to the patient at first it often leads to cystitis and renal complications Later, difficulty in starting micturition and nocturnal incontinence are common Acute retention of urine is sometimes the symptom which first brings the patient under observation but retention at any stage of the disease may be attributable to enlargement of the prostate, and removal of the latter may give complete relief Sexual desire and power are usually lost early in the course of the disease

OCULAR DISTURBANCES —While manifestations referable to spinal root disturbances are developing certain others arise in the areas supplied by the cranial nerves The most important are abnormalities in the reactions size and outline of the pupils and pupillary disturbances of some kind are often the first signs of the malady The Argyll Robertson pupil is the most characteristic abnormality *but it is not common* in its pure form namely, a very small pupil which reacts *normally to convergence* but *not at all to* light, and does *not dilate fully under the influence of a mydriatic* (see p 1343 1466) Absence *of the light*-reaction in one or both pupils with or *without retention* of the convergence reaction is usual and atrophic changes in the irides are very common

The size of the pupils varies greatly in different cases Most often they are small, but pupils of moderate size are common and sometimes they are widely dilated though this is very exceptional and is usually associated with optic atrophy *It is* not unusual to see pupils which when contracted to accommodation are *not much* larger than the head of a pin but the pin-point pupils are rare *Inequality of the pupils or irregularity in their outline is present in most* cases In old tabetics in whom the disease has been *present for very many* years the pupils may be found *wholly inactive* both *to light and* on convergence Partial bilateral ptosis usually

it is usually impossible to determine the sequence and duration of the signs that are found but if the onset of lightning pains and of ataxia are taken as landmarks an idea of the extreme variability of the course of tabes in different cases will be obtained In many patients the disease remains stationary in an early stage and causes no disability In a larger number however, inco-ordination appears after a pre ataxic stage of 10 or 20 years Some become ataxic within 5 years of the onset of pains a few within a year Once ataxia appears its rate of increase varies within wide limits It may be so rapid that walking becomes impossible in a few weeks it often increases very slowly, and only interferes seriously with walking after several years while in a large number periods of increase alternate with long periods in which the symptom is either stationary or undergoes temporary amelioration

The course of the other symptoms is equally variable In general irritative phenomenon—pains and crises—tend to diminish while the manifestations of destruction of afferent fibres—diminished sensation hypotonia etc.—increase Ocular palsies are frequently of short duration and bladder and rectal symptoms are often temporary It is impossible to foretell how any given case will progress but there seems to be some connection between the period which has elapsed since syphilis was contracted and the rate of evolution of the disease—the longer the former the more benign the course If the symptoms have increased slowly in the past the future course is likely to be slow whereas cases of rapid onset often progress rapidly When optic atrophy occurs blindness usually results eventually and a proportion of these cases develop general paralysis of the insane

The prognosis as to life is variable. Most tabetics die of intercurrent maladies, or of some cardio-vascular complication In many cases as the result of efficient treatment, the malady undergoes arrest and the patient may never become ataxic or grossly disabled Such arrest may also be found in benign cases in persons who have at no time had any antisyphilitic treatment Conversely treatment is not always successful and tabetics who have been rigorously treated may become progressively disabled On the whole the prognosis as to both working capacity and life is best in those cases in which the bladder can be kept free from infection

Treatment.—PROPHYLACTIC —This is on exactly the same lines as the preventive treatment of neurosyphilis in general The diminution in the incidence of tabes dorsalis suggests that the present methods of treating syphilis in its early stages are much more effective in preventing tabes dorsalis than in preventing other forms of neurosyphilis

SPECIFIC —When tabes dorsalis is associated with a positive Wassermann reaction in the blood or in the cerebrospinal fluid the specific treatment is the same as that described for general paralysis Pyrexial treatment by short wave therapy (but not by malaria) may occasionally be advisable either because of persistent severe lightning pains or of abnormalities in the cerebrospinal fluid which are not abolished by repeated courses of penicillin.

When the Wassermann reaction is negative in the blood and cerebrospinal fluid it is sometimes difficult to judge how much antisyphilitic treatment should be given and the decision must depend on the clinical indications of activity of the disease Lightning pains show that the disease is active Even after all clinical evidence of activity has ceased it is well to give the patient three or four times a year a month s course of a mixture of potassium iodide and liquor hydrarg perchlor

TREATMENT OF SYMPTOMS —*Pains* —These may be relieved with aspirin and other analgesic drugs Morphine should not be employed A course of antisyphilitic treatment usually reduces or stops the pains for a long time Exposure to cold sometimes seems to precipitate or aggravate pains and should be avoided as far as possible In severe and intractable cases the operation of spino thalamic cordotomy is justified

Ataxia —This can be greatly diminished in many patients by a course of Frenkel s exercises Just as a normal person by practice and effort can learn to perform feats

Diagnosis —Tabes dorsalis is diagnosed by its clinical features Examination of the blood and cerebrospinal fluid may not provide any evidence of syphilis, the Wassermann reaction is negative in one or the other in about 30 per cent of cases and completely negative in both in about 15 per cent. The diagnosis rests on (1) lightning pains, (2) characteristic sensory signs, (3) the Argyll Robertson pupil in one or both eyes (4) absence of one or both ankle or knee jerks, or a definite *diminution* in one of them and (5) evidence of syphilis.

Patients rarely seek advice until the clinical manifestations are fairly well established unless their early pains are severe or gastric crises occur Even then it is nearly always found that the pupils are abnormal, the ankle jerks are absent and hypalgesia is present over some of the characteristic areas The knee jerks may still be present and even normal, but this should not interfere with the diagnosis if the ankle-jerks are absent

Disseminated sclerosis often causes ataxia in the gait and may even in rare instances cause absence of the ankle-jerks, but signs of involvement of the pyramidal tract are usually definite the light reflex of the pupil is retained, and superficial sensory loss if any has not the distribution and the selective character that are typical of tabes dorsalis

Friedreich's ataxia is distinguished from tabes by the presence of pyramidal tract signs, dysarthria, nystagmus pes cavus and usually some degree of scoliosis Juvenile tabes is the most likely to be mistaken for Friedreich's disease

The effects of cerebellar ataxia are usually pronounced in the upper limbs and in the articulation as well as in the gait the pupils are not affected, the tendon jerks though possibly diminished are not absent and there is no sensory loss and no sphincter disturbance Because of these features the differential diagnosis from tabes is usually easy

Peripheral neuritis causes loss of tendon jerks and diminished sensation over the peripheral parts of the limbs, and frequently causes ataxia but there is usually also a loss of power in the extremities and possibly wasting there is no sensory loss on the chest and nose the pupils are not affected and in many cases the calves are very tender instead of being insensitive to pressure as they are in tabes

Subacute combined degeneration of the cord associated with pernicious anæmia gives rise to ataxia, and loss of the ankle jerks and knee jerks, but the plantar reflexes are extensor, and the blood picture is that of pernicious anæmia although the anæmia *may not be pronounced*

There are two groups of cases between which the diagnosis is especially difficult and in an individual case may be impossible On the one hand there is a group of cases of mild tabes occurring in adults but due to congenital infection in which the blood Wassermann reaction is negative and the cerebrospinal fluid is completely normal and on the other the group of non syphilitic cases described by Foster-Moore and by Adie in which the patients have ' tonic ' or ' pseudo-Argyll Robertson ' pupils and absent tendon jerks (see p 1344) In the former group the typical patient is undersized and of poor physique He comes under observation as a rule for some symptom which is not tabetic fits being a frequent presenting feature one or both pupils may be of true Argyll Robertson type and probably irregular in outline and lightning pains mild bladder trouble or some other feature of tabes may be present A family history of syphilis may be obtained The typical patient in the other group is of normal physical development The pupillary abnormality is probably limited to one eye and the patient may be able to give a history of its onset The irides look healthy Apart from the abnormal pupil and some absent tendon jerks the patient presents none of the multitudinous signs of tabes and there is no history of syphilis in the family or in the individual.

Course and Prognosis —In most instances tabes dorsalis is well established before some serious symptom brings the patient under observation. For this reason

it is usually impossible to determine the sequence and duration of the signs that are found but if the onset of lightning pains and of ataxia are taken as landmarks an idea of the extreme variability of the course of tabes in different cases will be obtained In many patients the disease remains stationary in an early stage and causes no disability In a larger number however inco-ordination appears after a pre ataxic stage of 10 or 20 years Some become ataxic within 5 years of the onset of pains a few within a year Once ataxia appears its rate of increase varies within wide limits It may be so rapid that walking becomes impossible in a few weeks it often increases very slowly and only interferes seriously with walking after several years while in a large number periods of increase alternate with long periods in which the symptom is either stationary or undergoes temporary amelioration

The course of the other symptoms is equally variable In general irritative phenomenon—pains and crises—tend to diminish while the manifestations of destruction of afferent fibres—diminished sensation hypotonia, etc.—increase Ocular palsies are frequently of short duration and bladder and rectal symptoms are often temporary It is impossible to foretell how any given case will progress but there seems to be some connection between the period which has elapsed since syphilis was contracted and the rate of evolution of the disease—the longer the former the more benign the course If the symptoms have increased slowly in the past the future course is likely to be slow whereas cases of rapid onset often progress rapidly When optic atrophy occurs blindness usually results eventually and a proportion of these cases develop general paralysis of the insane

The prognosis as to life is variable Most tabetics die of intercurrent maladies or of some cardio vascular complication In many cases as the result of efficient treatment, the malady undergoes arrest and the patient may never become ataxic or grossly disabled Such arrest may also be found in benign cases in persons who have at no time had any antisyphilitic treatment Conversely treatment is not always successful and tabetics who have been rigorously treated may become progressively disabled On the whole the prognosis as to both working capacity and life is best in those cases in which the bladder can be kept free from infection

Treatment.—PROPHYLACTIC —This is on exactly the same lines as the preventive treatment of neurosyphilis in general The diminution in the incidence of tabes dorsalis suggests that the present methods of treating syphilis in its early stages are much more effective in preventing tabes dorsalis than in preventing other forms of neurosyphilis

SPECIFIC —When tabes dorsalis is associated with a positive Wassermann reaction in the blood or in the cerebrospinal fluid the specific treatment is the same as that described for general paralysis Pyrexial treatment by short wave therapy (but not by malaria) may occasionally be advisable either because of persistent severe lightning pains or of abnormalities in the cerebrospinal fluid which are not abolished by repeated courses of penicillin

When the Wassermann reaction is negative in the blood and cerebrospinal fluid it is sometimes difficult to judge how much antisyphilitic treatment should be given and the decision must depend on the clinical indications of activity of the disease Lightning pains show that the disease is active Even after all clinical evidence of activity has ceased it is well to give the patient three or four times a year a month s course of a mixture of potassium iodide and liquor hydrarg perchlor

TREATMENT OF SYMPTOMS —*Pains* —These may be relieved with aspirin and other analgesic drugs Morphine should not be employed A course of antisyphilitic treatment usually reduces or stops the pains for a long time Exposure to cold sometimes seems to precipitate or aggravate pains and should be avoided as far as possible In severe and intractable cases the operation of spino thalamic cordotomy is justified

Ataxia —This can be greatly diminished in many patients by a course of Frenkel s exercises Just as a normal person by practice and effort can learn to perform feats

of balance and muscular co ordination which are impossible for one untrained so the tabetic by concentrating his attention on his movements can be taught to make greater use of his remaining powers and the results of re educative treatment are often astonishing In the more severe cases and when the patient is confined to bed, Frenkel s bed exercises should be employed Constant supervision of the re educative exercises is essential and the treatment should begin in an institution or under the supervision of a skilled attendant

Bladder disturbances—When there is any difficulty in passing water a mixture containing 5 minims of liq strychnine thrice daily will be found useful When the bladder is imperfectly emptied the use of the catheter should not be delayed Only too often neglect of this matter leads to death from pyelo nephritis It is well to re member that serious infections may run a painless course and their presence must be sought for even when pain is absent This entails an examination of the urine from time to time for evidence of inflammation in the urinary tract If pus cells are present in the urine chemotherapy should be tried and if this is unsuccessful the bladder should be irrigated daily until the urine becomes normal True incontinence of urine is often diminished by 5 minim doses of tincture of belladonna thrice daily or by the use of the following pill ℞ Ergotin (Bonjean) gr 1 Ext Belladonn gr ¼ Ft Pil Sig 1 t d s p c

Crises—Gastric crises, like the pains, are very resistant to treatment The follow ing should be tried Tinch chlor et morph co min 10 to 15 bismuth carb gr 15 Ac hydrocyan dil min 5 aq ad fl oz ½ Ft mist sig One tablespoonful to be taken in water every 3 or 4 hours Ephedrine, gr. ¼ or gr. 1 may also afford relief and may be given alternately with the mixture The use of morphine is not justified Rectal crises are sometimes relieved by small doses of grey powder with opium or pulv ipecac et opii The lower bowel should be emptied daily by enemata In mild cases with morning diarrhœa an enema or a suppository should be used before the first evacuation Thereafter the patient should try to resist the desire to defæcate which soon passes away and with a little training this troublesome symptom can usually be overcome Laryngeal crises, though very alarming are practically never fatal They are usually relieved at once by an inhalation of nitrite of amyl.

Optic atrophy—As soon as syphilitic optic atrophy is recognised energetic anti syphilitic treatment is urgently called for and for this condition particularly the use of penicillin has largely superseded other measures No time should be lost in instituting penicillin therapy but it should be started cautiously with doses of 10 000 to 15 000 units at 6 hourly intervals during the first day and unless the case is an acute one should be preceded for a day or two by the administration of potassium iodide and mercury by mouth, as described for general paralysis of the insane The dosage of penicillin should be increased rapidly to at least half a million units daily and a total of 10 million units should be given mercury and potassium iodide being continued meanwhile and for some weeks afterwards In acute cases and especially when one eye is already blind sympathectomy by excision of the stellate ganglion has been used for the purpose of increasing the circulation to the optic nerve on the better side Previously malarial treatment was commonly used and some authorities still prefer to use this or some other pyrexial treatment as well as penicillin but it is doubtful whether this is of additional benefit and the results obtained by various observers with penicillin alone are much better than those which preceded the intro duction of this remedy

After such a course of treatment the deterioration of vision is usually retarded and in favourable cases is arrested but the patient must be kept under close super- vision and any exacerbation of his visual symptoms should be regarded as a call for further treatment on the same lines as before If the Wassermann reaction remains positive in the blood the older antisyphilitic remedies may be employed but arsen icals should be used judiciously and doses of 0 6 g of neoarsphenamine should not

be exceeded tryparsamide should not be given because of its toxic effect on the optic nerve fibres

Charcot's joints —As soon as this condition is discovered the patient should be put to rest the joint immobilised and those measures used which tend to relieve the œdema and the effusion into the joint, and if occasion demands the joint should be aspirated When the joint becomes dry it should be rested for a long period Arthrodesis is the most satisfactory treatment for the knee joint In the case of the hip joint a satisfactory result is obtained with a caliper

Perforating ulcers —These should be curetted and dressed with a paste of iodine and starch

OTHER FORMS OF SPINAL SYPHILIS

ACUTE TRANSVERSE MYELITIS

This condition is now fortunately rare in England The patients are almost invariably males between the ages of 30 and 45 and the malady usually arises within a few years of infection but it may come on at any time

Over one or two segments of the spinal cord there is intense infiltration with small round cells and red cells and there may be small areas of softening The surrounding meninges show similar local infiltration

The symptoms are identical with those of acute transverse myelitis due to other causes (see p 1542) and the ætiological diagnosis depends on the discovery of evidence of syphilis As the onset is usually within a few years of the first infection the pupils are usually normal or not affected in any characteristic way a history of syphilis is often obtainable the Wassermann reaction is positive in the blood or cerebro spinal fluid and usually in both

Treatment with penicillin should be instituted carefully in all cases without waiting for the results of laboratory tests and when the presence of syphilis is con firmed it is probably helpful to add mercury and potassium iodide to the treatment (see p 1461) A course of ten million units of penicillin is sufficient to eliminate the infection but much of the damage to the spinal cord is of a permanent nature

The first sign of recovery is usually some return to muscular tone in the lower limbs and this is followed by the development of extensor plantar and of withdrawal reflexes Recovery of power and sensation continues slowly over many months but usually remains very incomplete

ERB'S SYPHILITIC SPASTIC PARAPLEGIA

This is a slowly developing condition which comes on many years after syphilitic infection The spinal cord shows degeneration of the pyramidal tracts and some marginal degeneration involving particularly the direct cerebellar tracts

Spasticity of the lower limbs becomes pronounced with corresponding weakness and typical reflex abnormalities Sensory changes if any are slight but vesical disturbances are the rule Pupillary abnormalities may or may not be present

PACHYMENINGITIS HYPERTROPHICA CERVICALIS

In rare cases the dura mater in the cervical region undergoes a great gummatous and subsequently fibrous thickening and the arachnoid and pia also become thick ened and fused with it The new tissue compresses the nerve roots and weakness wasting and sensory loss gradually develop in the arms After a time the spinal cord is compressed and spastic paraplegia results

SYPHILITIC AMYOTROPHY

This closely resembles idiopathic progressive muscular atrophy (see Progressive Muscular Atrophy p 1554)

The spinal cord shows degeneration of the anterior horn cells, most pronounced in the cervical region, and also some syphilitic changes in the meninges and blood vessels

The pupillary changes suggestive of neurosyphilis are absent in most of the cases The muscular atrophy usually begins in the upper limbs, and, as a rule, the tendon jerks in the affected limbs are absent, the lower limbs may be normal, or may become spastic or show wasting or may merely lose their tendon jerks but in some cases the wasting muscles retain their tendon jerks Not infrequently there is some sensory loss of the tabetic type, and vesical disturbances are common.

The course may be steadily progressive, but in recent cases it is usually arrested by antisyphilitic treatment In others the condition may remain stationary for long periods

Treatment —*For all kinds of spinal syphilis* the antisyphilitic treatment is the same as that described for general paralysis of the insane and it should be controlled in the same way by examination of the cerebrospinal fluid

SUBACUTE AND CHRONIC SYPHILITIC MYELITIS

Synonym —Subacute and Chronic Spinal Syphilis

Ætiology —The less acute forms may appear within the same age period and at the same interval after infection as the more acute, but on the whole they appear later

Pathology —The meninges become adherent and considerably thickened They are infiltrated with small round cells especially round their vessels Similar infiltration is found round the vessels in the cord and along the septa Changes in the nervous elements in the cord are usually limited to degeneration of fibres round the periphery

Symptoms —After a period of pain in the back lasting weeks or months, there is a gradual development of spastic paraplegia The latter may at first be variable In most cases bladder control is impaired and this may be the first symptom There are usually some objective sensory disturbances in the lower limbs but they are generally slight in comparison with the motor disturbances and may involve only certain qualities of sensation *e g* appreciation of temperature or of vibration or sense of position in the toes Evidence of tabes dorsalis may be present in which case the knee jerks and ankle jerks may be absent, and the degree of spasticity is likely to be slight

Syphilitic meningitis may affect the cauda equina In that event it gives rise to a flaccid weakness of the parts below the knees and weakness or paralysis of the vesical and anal sphincters. Some sensory loss may be found over the characteristic area on the buttocks and perineum

Diagnosis —In the cases which occur within 5 years or so of infection the Wassermann reaction will almost certainly be positive in the blood or in the cerebrospinal fluid or in both In those which develop many years after infection the Wassermann reactions may be negative Pupillary abnormalities suggestive of neurosyphilis and sensory loss of the tabetic type on the chest arms and nose are likely to be present

Course and Prognosis —The former is very variable Some cases show considerable remissions and aggravations others a fairly steady deterioration The rate of increase of paralysis may be very slow or may lead to complete incapacity in a few weeks or months Eventually urinary infection and bed sores may develop

Antisyphilitic measures arrest the disease and usually bring about a fair degree of recovery

Treatment—This is the same as for other forms of spinal syphilis together with special precautions for the bladder weakness (see under Tabes) and symptomatic treatment of the paraplegia

SPINAL VASCULAR SYPHILIS

In rare cases the symptoms indicate that the chief incidence of the syphilitic disease is on the blood vessels of the spinal cord (see also Acute Syphilitic Transverse Myelitis on p 1469)

Thrombosis of a segmental branch of the anterior spinal artery gives rise to sudden paralysis of the muscles of one side deriving their nerve supply from the same segment of the cord *e g* paralysis of the deltoid and scapular muscles and weakness of the triceps brachii muscle when the fifth cervical segment is affected Similar paralysis in the opposite corresponding limb may occur within a few days If the main anterior spinal artery becomes thrombosed in the cervical region there is complete paralysis of both upper limbs with the exception of the hands Either at once or within a few days sensory loss to pain and temperature appears in the arms The muscles waste and the clinical picture resembles that of syringomyelia The tracts of the cord are little affected and abnormal signs in the lower limbs are absent or slight The Wassermann reaction is likely to be strongly positive in the blood but may be negative in the cerebrospinal fluid

At necropsy softening or cavitation within the cervical enlargement is found

The treatment is the same as that of other forms of meningo vascular syphilis

CONGENITAL SYPHILIS OF THE NERVOUS SYSTEM

Affections of the nervous system are much less frequent in congenital syphilis than in the acquired disease Viewed broadly the pathological changes and the clinical manifestations are the same in both Regarding the first meningitis endarteritis and gummata are common to both forms but while *softening* from arterial disease is characteristic of acquired syphilis *cortical cell atrophy and subsequent sclerosis* are prominent features in congenital cases As for the symptoms mental defects with convulsions and spastic weakness of the limbs, are typical of congenital syphilis in contrast to the hemiplegias and monoplegias with or without convulsions which occur in the acquired form It is noteworthy that the combination of obvious visceral and integumental lesions with parenchymatous degeneration of the nervous tissue, is very common in the congenital but not in the acquired disease

Symptoms—Many syphilitic infants suffer from convulsions during the first 2 years of life and in many cases these are given as the cause of death In those who survive fits may continue or they may begin again towards the end of childhood the latter being more common The fits in some cases have all the aspects of idiopathic epilepsy and may continue throughout life without the addition of any symptoms suggestive of local brain disease In another group convulsions are followed by symptoms of hemiplegia or of spastic diplegia, The same defects may appear apart from convulsions Hydrocephalus develops in some cases

Mental impairment is one of the common features of the disease Idiocy is rare More often the defect is first noticed between the ages of 5 and 15 years The child may merely cease to learn and retain any acquirements he possesses or he may lose his memory and become slowly demented

Vision is often defective as a sequel of atrophy of the optic nerve or of choroidoretinitis or simply of interstitial keratitis, and bilateral deafness is not uncommon Affections of the remaining cranial nerves are rare

Juvenile general paralysis appears most often between the ages of 10 and 17 years It has been seen as early as the eighth and as late as the thirtieth year In some cases it results from congenital syphilis in others from syphilis acquired in infancy or in childhood The physical signs are the same as in the adult form The mental symptoms as might be expected, differ from those in adults when mental decay sets in before the appearance of the instincts and passions which form the content of the delusions in older patients A boy of 12 for example is not likely to have delusions regarding his wealth or his intellectual capacity or his sexual powers although he may well have grandiose ideas concerning his physical strength Optic atrophy is very common in juvenile cases and as in adults, signs of tabes are present in many cases

Juvenile tabes presents the same features as in adults It is however, very uncommon in its pure form because most cases begin with optic atrophy and go on to tabo paresis It is important to remember that in rare instances tabes in an adult owes its origin to congenital syphilis or to syphilis acquired in infancy In such cases the blood and cerebrospinal fluid are usually normal

The diagnosis of congenital syphilis of the nervous system rarely causes any difficulty, as the patients almost invariably present some of the stigmata of their malady

One or more courses of penicillin should be given until the cell content of the cerebrospinal fluid becomes and remains normal and thereafter treatment by mercury should be carried on but the results are often disappointing

THE DEMYELINATING DISEASES

DISSEMINATED SCLEROSIS

Synonyms —Multiple Sclerosis, Insular Sclerosis

Ætiology —After intracranial new growths and cerebral vascular disease disseminated sclerosis is probably the commonest incapacitating disease of the nervous system having displaced in this country at least, syphilis of the nervous system It has its highest incidence in northern Europe, is less common in North America and relatively rare among the white population of the Southern hemisphere

Cases have been recorded in which the disease was first noticed after acute illnesses such as scarlet fever influenza and rheumatism but it is probable that these simply made more prominent a condition already present Febrile illnesses are usually followed by increase in the symptoms and many patients with disseminated sclerosis relate that they became much worse after an attack of influenza In the great majority of the cases there is nothing in the family or personal history to which the disease can be attributed In one instance confirmed by examination after death it attacked a mother and her child and a few similar cases as well as the affection of several members of a family or of a household have been recorded

The onset is most frequent between the ages of 16 and 30 the sexes being affected equally It is rare for the disease to begin after the age of 55

The cause is still wholly unknown There is no sure evidence that any of the demyelinating diseases of the nervous system are directly due to the action of a filtrable virus The signs of inflammatory reaction in this disease are compatible with the view that it is infective in origin but it may be added that it behaves like no known infective disease

Pathology —The disease has been described by Nageotte and Riche as an affection constituted by multiple inflammatory foci varying greatly in size and

number disseminated irregularly throughout the length of the cerebrospinal axis The chief features of these foci are (i) their sharp outline (ii) their irregular and capricious shape (iii) the fact that they do not interrupt the axis cylinders which are only demyelinated and deformed as they traverse the focus Hence the absence of Wallerian degeneration The abundance of neuroglia in the foci justifies the name sclerosis which has been given to the process

These foci are visible on naked eye examination the fresh ones as greyish translucent patches the older ones as greyish or pinkish shrunken areas Grey and white matter are both affected the foci having some predilection for the walls of the ventricles The foci bear no necessary relation to blood vessels

Under the microscope the older patches are found to contain proliferated neuroglia and nerve-fibres which have lost their myelin sheaths. The axis cylinders in the sclerosed areas escape destruction for a long time For this reason secondary degenerations do not occur in the spinal tracts and sections of the cord between lesions at different levels present normal appearances Ganglion cells are also spared, hence wasting of the muscles supplied by the affected segments is not a feature of the disease In recent patches œdema is present with infiltration by lymphocytes plasma cells and compound granular corpuscles around the blood vessels especially in the adventitial sheath of the veins It is highly probable that these inflammatory changes represent the initial lesion and that the alterations in the nerves and in the neuroglia are secondary to them

Symptoms—In the early stages the axis cylinders in the diseased areas are not interrupted completely but suffer partial and temporary impairment which alters in intensity with the severity of vascular and other inflammatory changes in the tissues around them Moreover as the inflammation subsides in one patch a new one develops and produces a different set of symptoms Hence it is not surprising that the earliest symptoms are often slight and fleeting or that they may first appear now in one part and now in another In spite of this however certain symptoms and physical signs appear with remarkable regularity and render disseminated sclerosis in the more advanced stages at least one of the most distinctive and most easily recognised diseases of the nervous system

It is remarkable that though the demyelinating lesions which are often of considerable size occur anywhere in the central nervous system and commonly involve the fillet the lateral fillet, the spinothalamic paths and the peripheral neurones in their intermedullary course and the visual path yet anything but the most transient loss of function seldom occurs in connection with these systems On the other hand the phylogenetically newer systems—the pyramidal paths and the proprioceptive system commonly suffer permanent damage The optic nerve is a common site for the development of an area of the disease This may be situated anywhere between the globe and the optic chiasma and produce the very characteristic picture of acute unilateral retrobulbar neuritis

Motor Symptoms.—Weakness in the lower limbs is the symptom for which many patients first seek relief. Beginning with a feeling of heaviness or stiffness in one or both limbs the weakness, which may be limited at first to one group of muscles increases in some uniformly in a large number with remissions or with periods of apparent recovery until at last after a time which varies from a few weeks to many years, it ends in severe spastic paraplegia. The physical signs are those of pyramidal lesions in general—increased tone in the muscles and exaggeration of the tendon reflexes diminution or loss of the abdominal and cremasteric reflexes and Babinski s plantar response They are of extreme importance for some or all of them may be present when the patient s complaints are still trivial and they are found so constantly in all stages of the disease that the diagnosis of disseminated sclerosis is rarely made in their absence

The paralysis can often be distinguished from that of other pyramidal affections

Juvenile general paralysis appears most often between the ages of 10 and 17 years It has been seen as early as the eighth and as late as the thirtieth year In some cases it results from congenital syphilis in others from syphilis acquired in infancy or in childhood The physical signs are the same as in the adult form The mental symptoms as might be expected differ from those in adults, when mental decay sets in before the appearance of the instincts and passions which form the content of the delusions in older patients A boy of 12 for example is not likely to have delusions regarding his wealth or his intellectual capacity or his sexual powers although he may well have grandiose ideas concerning his physical strength Optic atrophy is very common in juvenile cases and as in adults signs of tabes are present in many cases

Juvenile tabes presents the same features as in adults It is however, very uncommon in its pure form because most cases begin with optic atrophy and go on to tabo paresis It is important to remember that in rare instances, tabes in an adult owes its origin to congenital syphilis or to syphilis acquired in infancy In such cases the blood and cerebrospinal fluid are usually normal

The diagnosis of congenital syphilis of the nervous system rarely causes any difficulty as the patients almost invariably present some of the stigmata of their malady

One or more courses of penicillin should be given until the cell content of the cerebrospinal fluid becomes and remains normal and thereafter treatment by mercury should be carried on but the results are often disappointing

THE DEMYELINATING DISEASES

DISSEMINATED SCLEROSIS

Synonyms —Multiple Sclerosis Insular Sclerosis

Ætiology —After intracranial new growths and cerebral vascular disease disseminated sclerosis is probably the commonest incapacitating disease of the nervous system having displaced in this country at least, syphilis of the nervous system It has its highest incidence in northern Europe, is less common in North America and relatively rare among the white population of the Southern hemisphere

Cases have been recorded in which the disease was first noticed after acute illnesses such as scarlet fever influenza and rheumatism but it is probable that these simply made more prominent a condition already present Febrile illnesses are usually followed by increase in the symptoms and many patients with disseminated sclerosis relate that they became much worse after an attack of influenza In the great majority of the cases there is nothing in the family or personal history to which the disease can be attributed In one instance confirmed by examination after death, it attacked a mother and her child and a few similar cases, as well as the affection of several members of a family or of a household have been recorded

The onset is most frequent between the ages of 16 and 30, the sexes being affected equally It is rare for the disease to begin after the age of 55

The cause is still wholly unknown There is no sure evidence that any of the demyelinating diseases of the nervous system are directly due to the action of a filtrable virus The signs of inflammatory reaction in this disease are compatible with the view that it is infective in origin but it may be added that it behaves like no known infective disease

Pathology —The disease has been described by Nageotte and Riche as an affection constituted by multiple inflammatory foci varying greatly in size and

Double vision in a young person should always arouse the suspicion of disseminated sclerosis, and if it is associated with signs of pyramidal tract disease, the combination makes the diagnosis almost certain

Strabismus is uncommon Even when the patient is seen whilst complaining of double vision it is unusual to detect any limitation in the range of the ocular movements *Ptosis* is rare

Nystagmus is present in more than half the cases but not so frequently as an early sign It is usually fine rapid and horizontal appearing only when the eyes are directed to the side In some cases the eyes oscillate constantly whatever their position Except in rare cases there is no apparent movement of objects even when the oscillations are of wide range

Visual failure —Diminution of visual acuity due to lesions in the optic nerves—retrobulbar neuritis—occurs sooner or later in many cases It may precede all other symptoms by a period of several years As in the case of the other symptoms it is subject to exacerbations and periods of improvement A young healthy person complains of rapidly increasing mistiness of vision, usually in one eye sometimes in both or in one after the other reaching its maximum in a few hours or days this is often preceded or accompanied by pain about the orbit, which is increased on moving the eye In the common unilateral case the signs are those of a lesion in one optic nerve, the pupil on the affected side is larger than its fellow its direct reaction to light is impaired but it contracts well consensually Tests with a small object preferably coloured reveal a central scotoma At the onset the disk is usually normal but in a few instances the inflammation reaches the nerve head in which event the disk is blurred and swollen Later the disk may be pale or normal Rapid improvement of vision is the rule Special tests may reveal a persistent slight loss of visual acuity and a partial central scotoma or very rarely a complete central scotoma Subsequent acute attacks are common In some cases the onset of visual failure is gradual Usually the defect is slight but it may be serious although complete blindness never occurs In these cases the disk is pale especially in its temporal portion, and the field shows a central scotoma or narrowing at the periphery

Mental Symptoms —Defective memory and slight impairment of intellectual power are common Some of the patients are morose and subject to fits of depression, but the majority are surprisingly cheerful and do not seem to suffer mentally even when their physical state is most pitiable This unjustified cheerfulness is called euphoria In many cases there is considerable loss of emotional control and ready laughter or weeping is fairly common More often there is merely a tendency to laugh at trivial things

Sphincter Disturbances —These troubles arise from interference with the long paths in the spinal cord by which volitional consent and inhibition are held upon the act of micturition Therefore lack of control in the form of hesitancy and precipitancy are common and retention may occur In rare cases control over the rectal sphincter is lost

Other Symptoms —Deafness giddiness and tinnitus sometimes with repeated vomiting are common Epileptiform convulsions are rare In most instances the distribution of the signs will indicate that the lesions are multiple but sometimes although the patches are numerous the signs are those of a single lesion say of the internal capsule of the mid brain or of the cerebellum

Cerebrospinal Fluid —In many cases even when the disease is in an active phase the fluid is normal In others there may be a moderate increase in protein not usually more than 80 mg per cent and a lymphocytic pleocytosis of 10 to 30 per c mm The Lange colloidal gold test is negative in about half the cases In the other half the test is positive and may be of the luetic or paretic type The latter variety may be strongly marked and when occurring in association with a negative Wassermann reaction is very suggestive of disseminated sclerosis

by the variations in its severity from time to time and by the occurrence of remissions or of apparent recovery the improvement sometimes lasting for weeks or months and in rare cases for many years In most cases moreover examination will reveal some other sign—nystagmus intention tremor, or pallor of the disk—which betrays the cause of the paralysis. In one large group of cases particularly common when the disease begins *after the age of 35, the symptoms are those of a steadily increasing* spastic paraplegia without remissions and without any indication, either in the physical signs or in the history of extra pyramidal disease The gait may be but slightly altered even when the tendon reflexes are greatly exaggerated and the plantar responses are extensor Later, it becomes spastic or spastic and ataxic Sometimes ataxy makes walking very difficult, when the power in the limbs is only slightly impaired In the arms there is often loss of power associated with exaggeration of the tendon reflexes *In some cases the arms are affected before the lower limbs* when astereognosis and loss of sense of position from a lesion in the course of the corresponding posterior column of the cord produce one of the commonest of the early symptoms—the useless arm

Tremor —The characteristic tremor in the arms appears on voluntary movement only and increases in rate and amplitude as the goal is approached For these reasons it is called intention volitional or terminal tremor It is sought for by causing the *patient to touch his nose with the tip of one finger In its minimal form the tremor* appears as two or three jerky movements of the finger just as the goal is attained or the finger reaches the nose without any abnormal movement and then oscillates so that it slips away from the nose again or depresses it several times before coming to rest The tremor may be noticed first in writing or in performing other delicate movements such as threading a needle Later the rate and amplitude of the movements increase, and the tremor, although still greatest at the end appears almost as soon as a voluntary *movement begins In advanced cases it prevents all useful* movements and the patient is unable to do anything for himself The arms are affected earliest and most often but nodding of the head is common and any part of the body may be affected Beside intention tremor other types of inco ordination of the limbs are occasionally seen such as those characteristic of lesions of the optic thalamus or of the mid brain or of the cerebellum

Sensory Symptoms —*Subjective* —Numbness and tingling in the extremities and alterations in the sensation of various parts are common complaints. They are often transient and may be the only symptoms during the premonitory period Severe pains are rare, but many patients complain of stiffness or of aching in the limbs and in the back Occasionally intense neuralgic pain of trigeminal nerve distribution is found

Objective —Severe cutaneous sensory loss is not common, but careful examination will often reveal areas of skin in which sensation is impaired Occasionally the loss is severe and may show so sharp an upper level as to suggest the presence of a spinal tumour In many cases the sense of position and passive movements in the limbs is seriously affected in others loss of vibration sense is the only sensory sign An isolated loss of the last named in the legs is a phenomenon of diagnostic importance. Like *the other signs the sensory disturbances often show* considerable variations in extent and degree at different examinations

Ocular Symptoms —Attacks of *double vision* are frequent and highly characteristic of the disease. Close interrogation avoiding the leading question if possible will often elicit an account of these attacks *when the patient has not* mentioned them at first either because he has forgotten them or because it does not occur to him that a symptom so remote or so transient can have any bearing on his present trouble This diplopia is of the highest importance because it is often the sole complaint when the patient seeks advice for the first time and because its presence *or a history* thereof is often the deciding factor in the diagnosis of early cases with spinal symptoms

5 *Spinal syphilis* may also produce a paraplegia of variable onset which may be associated with evidence of scattered lesions elsewhere in the nervous system An examination of the blood and spinal fluid will usually clear up any doubt

6 *Cervical spondylosis* in middle aged and elderly subjects may give rise to a fluctuating lesion of the cervical cord which is very apt to be misdiagnosed as disseminated sclerosis

Course and Prognosis—Despite the remarkable fluctuations which may mark its course the disease ultimately disables the sufferer and is the cause of his death Nevertheless it is important to remember that after the initial outbreak of symptoms some patients regain normal physical capacity lose all abnormal physical signs and lead a normal life for several years 5 10 and 15 year periods of this kind are by no means rare and in general it may be said that the period of evolution of the disease is longer than is generally supposed On the other hand a few cases run a rapidly downhill course from the onset The later in life disseminated sclerosis makes its first appearance the more benign its course and sufferers may be found who have reached old age without gross or total disablement Commonly after two or three fresh exacerbations with intervening recoveries of greater or less completeness a slowly increasing permanent disability sets in It is not possible to say that those cases which run the longest and less distressing course owe this to treatment for many untreated cases fare relatively well But there are certain factors which do appear to influence its course unfavourably in most though not in all instances—thus intercurrent illness especially if it be febrile injuries which disable the patient for a short period, all surgical interventions—including the therapeutic interruption of pregnancy which is designed to avert the frequently seen exacerbations that follow the puerperium—and prolonged or recurrent physical exhaustion

Treatment—The behaviour of disseminated sclerosis makes the assessment of any mode of treatment extremely difficult and a failure to appreciate the wideness of its fluctuations and the length and completeness of some of its remissions is responsible for many therapeutic claims that in the hands of those best acquainted with this malady fail to justify themselves So far there is no remedy which exerts any constant or certain influence upon the course of the disease

The most important general considerations in treatment are to provide complete rest in bed during an acute relapse and to arrange for a sheltered life during periods of remission or when the disease has become established

Of drugs arsenic is the remedy which has had the longest vogue and many believe that it is of value though it cannot in any sense be regarded as curative It may be given as Fowler s solution starting with a dose of min 3 t i d and increasing it to min 8 t i d over a period of 3 to 4 weeks If this method is used it is best to stop all arsenic for a week at the end of each complete course Not every patient can tolerate doses larger than min 3 or min 4 three times daily This method is probably as useful as that of intramuscular injection but considerations of expediency may dictate the use of the latter method

A more recently employed drug is quinine hydrochloride in doses of gr 3 to 5 twice daily continued over a long period Here again intolerance may intervene and prevent this Periodic courses of quinine bismuth iodide have also been advocated Other recent forms of medication include liver therapy pyrexial therapy, protein shock therapy and vaccine therapy None of these has justified itself and when it is recalled that a febrile illness commonly aggravates the severity of disseminated sclerosis it is scarcely surprising that pyrexial therapy should sometimes have the same result

The fact that disseminated sclerosis is sometimes—though not always—adversely affected by a confinement has led to the increasing advocacy of terminating pregnancy at the third month to avert this ill effect But this procedure is exposed to the same objection as a full term delivery or any surgical procedure and sometimes has the

Diagnosis —The combination of spastic weakness of the legs with Charcot s triad of symptoms—namely intention tremor nystagmus and scanning speech—which is so widely and so erroneously regarded as characteristic of the disease and as necessary to its recognition is rarely seen except in the later stages of disseminated sclerosis As this malady usually presents itself to us in its initial stages when it may and should be diagnosed it commonly consists in a group of signs of involvement of the pyramidal tracts namely increased tendon jerks Babinski plantar responses absent abdominal reflexes a little weakness of dorsiflexion of one or both feet possibly also some weakness of flexion of the proximal segments of the lower limbs and usually a degree of impairment or loss of vibration sense over the malleoli. In many cases this is all we can find, but in an otherwise healthy young adult it is a syndrome more likely to be due to disseminated sclerosis than to any other pathological process

Perhaps there may be confirmatory signs such as a little nystagmus, slight intention tremor or sensory ataxy of an arm it may be pallor of the temporal half of one or of both disks—a pathognomonic sign. If some or all of these signs have as it were been arrived at after such a fluctuating course as we have seen to be so typical of most cases of disseminated sclerosis, then diagnosis can be no longer in doubt and it is comparatively seldom that pathological examinations of blood or cerebro spinal fluid are really necessary for this end

When after some years, the disease is fully developed it still retains its individuality The patient is commonly euphoric there is frequently tremor of the head, and sometimes of the whole body when the patient tries to stand or walk The arms are unsteady the legs spastic and weak—sometimes showing a tendency to pass into the condition of paraplegia in flexion There is little sphincter control left but cutaneous sensibility is commonly almost or quite intact

At whatever stage disseminated sclerosis comes under observation a careful enquiry into the history of the illness is important and to elicit this requires a knowledge of the natural history of this disease as it has been outlined here

Disseminated sclerosis has to be diagnosed from various diseases of which we will consider the following

Hysteria —The serious mistake of attributing the early symptoms of this relentless disease to hysteria can be avoided by the taking of an accurate history combined with a careful examination of the nervous system Pallor of the disk absence of the abdominal reflexes or a distinct difference between them at corresponding points on opposite sides unequal exaggeration of one or more of the tendon reflexes when compared with their fellows an extensor plantar response on one or both sides—any one of these signs alone would render a diagnosis of hysteria untenable

Compression of the cord.—When the signs in disseminated sclerosis are purely spinal the diagnosis from *spinal tumour* presents real difficulties The first may be mistaken for the latter when the paralysis increases steadily without remissions and is associated with sensory loss extending upwards to a definite level while the reverse error may be made when the symptoms caused by a tumour are purely motor or vary in intensity or are associated with nystagmus

Friedreich s ataxia.—This may be suggested by the presence of ataxy in a young patient with disseminate sclerosis The distinction can be made at once for in the latter disease the tendon reflexes in the lower limbs are exaggerated whereas they are lost early in Friedreich s disease

Subacute combined degeneration of the cord —In the rare cases where disseminated sclerosis has its onset in middle aged subjects the combination of manifestations indicative of involvement of the posterior and lateral columns of the cord together with the presence of paraesthesia may closely simulate subacute combined degeneration. Investigation of the blood for changes of pernicious anæmia and of the gastric juice for free HCl will usually render the differential diagnosis certain

may become stationary and in rare instances proceed to complete recovery of both power and of vision or the subject may be left with disability of varying severity

The paraplegia is that characteristic of a diffuse spinal lesion in that there is sensory loss, paralysis and loss of sphincter control

Treatment—No treatment has any clear influence upon the course of events Arsenical preparations have been employed—as for disseminated sclerosis The management of the case is that of any case of paraplegia

HEREDITARY AND FAMILIAL DISEASES

1 FRIEDREICH S ATAXIA

Synonyms—Friedreich s Disease, Hereditary Ataxia

Definition—An hereditary disease characterised clinically by a progressive ataxia and pathologically by the degeneration in the spinal cord of the posterior columns lateral columns (pyramidal tracts) and spino cerebellar tracts and in the cerebellum of a number of the Purkinje cells

Ætiology—Transmission occurs both through the males and the females In direct heredity is the most common for the reason that the subjects of this disease are usually afflicted in childhood and incapacitated by the time adult life is reached and therefore they do not procreate Direct heredity is however by no means so uncommon as has been supposed Isolated cases in which no heredity can be traced are not rare The first signs of the disease usually appear in early childhood and before the sixth year but symptoms may not be evident until a few years later In a considerable number of cases however the onset is delayed until the time of puberty while in a few examples it may be delayed until after the age of 30 years As a rule the age incidence is approximately the same in each child rank of the same family but sometimes the phenomenon of ' anticipation is well marked the disease appearing at an earlier age in each succeeding generation The disease is said to be slightly more common in males

Pathology—The spinal cord is unusually small and apparently this smallness may be congenital and the posterior roots tend to be small grey and poorly myelinated The essential change is a primary degeneration of certain neurones in the dorsal column of the spinal cord of the pyramidal tracts and of the spino cerebellar tracts both dorsal and ventral This degeneration commences first in the periphery of the axon which slowly dies back towards the nutrient cell body

The degeneration of the dorsal columns is usually the earliest change and remains the most prominent feature throughout The degeneration of the fibres of the pyramidal tract appears later

The spino cerebellar tracts are constantly degenerated the direct cerebellar tract being the most seriously involved The cells of Clarke s column from which the direct cerebellar tract takes origin and around which the pyramidal tracts end degenerate and disappear as does also the network of collaterals which surrounds these cells Consequent upon these degenerations and secondary to them well marked neuroglial proliferation or sclerosis occurs The cerebellum may be normal or it may show varying degrees of atrophy of Purkinje s cells or of any other of its cell elements and of the tracts connected therewith

Symptoms—The onset is always insidious and physical signs of abnormality usually precede any complaint on the part of the patient or his relatives The first symptoms are generally complained of between the sixth and the tenth year of child hood but if a careful examination be made of the younger members of the families upon which Friedreich s disease is incident, physical signs of the disease especially

same unfortunate influence upon the course of the malady It is therefore not a therapeutic measure that can be justified by its results The correct procedure is to take every possible measure to maintain the health and nutrition of the pregnant woman and to afford her at this time and after the puerperium more than the ordinary amount of rest This is the rational, if not always the acceptable line of treatment Further women suffering *from the disease in an active phase should* be advised against becoming pregnant

Of great importance is the right ordering of the patient s life when practicable, and the avoidance of fatigue in the early stages of the disease

OTHER DEMYELINATING DISEASES OF THE NERVOUS SYSTEM

There exist a number of other diseases of the central nervous system having considerable pathological affinities with disseminated sclerosis in that they depend upon a demyelinating process predominantly of the white matter which may be either diffuse or localised and predominantly cerebral or spinal in incidence

Of these disorders Schilder s disease in which the morbid process is confined to the brain (p 1412) and acute encephalomyelitis associated with acute specific fevers (p 1411) the incidence of which may fall on either the brain or spinal cord or upon the two together *have already been considered in the article on encephalitis*

There remains for consideration the syndrome of neuromyelitis optica.

There are points of considerable resemblance between these three disorders and disseminated sclerosis particularly as regards their pathology but there are equally significant points of difference and whether or not they are ætiologically related cannot at present be affirmed

NEUROMYELITIS OPTICA

Synonyms —Diffuse Myelitis with Optic Neuritis Devic s Disease

Definition —A form of dis eminated myelitis preceded or accompanied by retrobulbar neuritis with or without papillœdema It is commonly acute in onset and may end in death or in arrest with residual disabilities Complete recovery is rare Persons of all ages from adolescence onwards may be affected

Ætiology —Nothing whatever is known of its causation and therefore it has been suggested that the disease is infective None of the neurotropic viruses is *known to produce the demyelination which is* the characteristic lesion of the disease nor is there any evidence that this is bacterial

Pathology —The spinal cord shows either diffuse or multiple disseminated lesions They may be confined to a few segments of the cord or may be found from end to end of this structure The essential feature of the lesions is a demyelinisation of axis cylinders There is also round celled perivascular infiltration an intense proliferation of microglial cells and a multiplication of tiny vessels in the affected areas The optic nerves *present the same type of lesion* namely an intense demyelinisation of the nerve fibres In general the pathological changes are more intense than those of disseminated sclerosis and show less evidence of partial remission

Symptoms —The blindness which indicates the optic nerve lesion may precede or may follow the appearance of paraplegic symptoms *The latter develop rapidly* and may spread upwards until sensory loss and muscular weakness reach the upper thoracic level Blindness with some swelling of the optic disk and central scotoma may ensue The patient may become progressively worse and die or the paralysis

first objective sign of the disease but in cases in which there is a major degeneration of the pyramidal tracts the knee jerks may persist or even be brisk into the advanced stages of the disease The abdominal reflexes gradually disappear The plantar reflex is invariably an extensor response The sphincters usually escape The cerebrospinal fluid presents no abnormality

Spinal curvature is very common and may reach a severe degree It consists of a scoliosis of the dorsal region and often with some kyphosis and with a compen satory reverse lumbar curve The cause of this deformity is probably the defect in the postural tone of the muscles

Diagnosis —In uncomplicated cases the diagnosis is a matter of no great diffi culty on account of the strikingly distinct nature of the symptoms Friedreich s disease can hardly be mistaken for tabes since the history of heredity the peculiar deformity of the feet and spine the extensor plantar reflex the speech affection and the nature of the ataxy contrast strongly with the loss of pain sensibility and of deep sensibility the pupillary changes the sphincter trouble the abnormal Wassermann reactions and the abnormal cytology of the cerebrospinal fluid in tabes The dis tinction from disseminated sclerosis presents more difficulty but in this disease the onset never occurs in childhood there is no heredity the deep reflexes are never lost and the spinal deformity does not occur

Course and Prognosis —The course of the disease is usually progressive in slow and irregular fashion and the prognosis is therefore in every case serious but the average duration of the disease is over 30 years and in some cases it seems to have no tendency to shorten life The prognosis is worse and the course more rapid in those patients who have shown disability from the time of learning to walk In some cases the disease appears to become arrested Intercurrent maladies febrile illnesses and debilitating influences generally may have an effect in hastening the advance of the disease and bringing about a fatal termination Confinement to bed from any cause whatever has a bad influence upon the ataxy and upon the capacity for walking

Treatment —No treatment is known which specifically affects the malady General tonic treatment and all measures which improve the general health and mental well being often have a surprising effect in improving the ataxy Re educa-tional training of the limbs and trunk in the form of Frenkel s exercises are most beneficial Properly designed boots to ensure the most advantageous use of the deformed feet must be provided

2 DELAYED CFREBELLAR ATROPHY

Of all the primary atrophies of the cerebellum it may be said that their ætiology is unknown but the cause probably endogenous In some forms there is clear evidence of heredo familial factors but not in all Some of them appear in early infancy while others manifest themselves in later life and are hence called delayed The infantile forms are extremely rare Of the delayed varieties much the least uncommon is an atrophy of the cerebellar cortex—*Marie s delayed cortical cerebellar atrophy*

Ætiology and Pathology —This disease affects both sexes and shows itself at any age from 45 onwards The lesion is bilaterally symmetrical and is most marked on the upper anterior parts of the cerebellum It is essentially a cortical atrophy with disappearance of the Purkinje cells as its characteristic feature Familial incidence has been described by Holmes and others

Symptoms —The clinical picture is that of a slowly developing ataxia of gait accompanied by a disorder of articulation ataxia of the upper limbs develops later but nystagmus rarely occurs In many cases the tendon jerks are exaggerated indi cating an element of spinal degeneration

the extensor response in the plantar reflex the retraction of the great toe and some degree of pes cavus may often be found before the sixth year

Ataxia is always the first sign to appear and this is shown by an awkwardness of gait and a tendency to stumble and fall readily Sometimes it is obvious from the history that the ataxy dates from the earliest years of infancy when it is said that the child was never strong on his legs from the time of learning to walk and that he could never run properly or join on equal terms with other children at play As the disease progresses the gait slowly becomes more irregular and clumsy The patient walks with his feet upon a broad base and staggers and reels from side to side but notwithstanding this he keeps a fairly direct line of progression He takes short steps which are unequal and which are irregular in relation to the line of progression and the movement of each foot as it is raised is poorly co ordinated There is never the undue excursion and noisy stamping of the feet which are so characteristic of the gait of tabetic patients

In standing the body oscillates from side to side in slow and clumsy fashion and coarse tremors of the head and trunk are constant features in advanced cases (titubation) Sometimes Romberg s sign is present but this is never so well marked as in tabes and it is frequently absent The ataxy invades the upper extremities as a rule, later than the legs There is first clumsiness with the finer movements and then little by little with all the movements It closely resembles the ataxia due to gross disease of the cerebellum and differs from that which occurs in tabes That irregular breaking of a movement towards the end of its accomplishment which has been long termed intention tremor ', is frequently seen

Irregular involuntary movements, often described as like those of chorea or of myoclonus occur in advanced cases and are most frequently seen in the head and neck as nodding movements and jerky tremors Nystagmus is usual it is generally seen with lateral deviation of the eyes and may be very irregular Dysarthria is almost constant and is gradually progressive At first the speech is of the slurred cerebellar type but with increasing ataxia it becomes scanning or drawling

The strength of movements is at first little impaired but as the disease advances and the pyramidal degeneration increases the power is gradually lost in proportion to the degree of the pyramidal degeneration which varies greatly in different cases The lower extremities are affected first and most and later the arms and in severe cases at a late stage paralysis may be almost universal

The condition of the muscular tone depends upon the relative degree of degenera tion in the posterior roots and in the pyramidal tracts respectively the former tending to abolish and the latter to increase it As a rule the influence of the posterior root degeneration is preponderant and therefore the limbs are flaccid and hypotonic but occasionally they are somewhat rigid Contractures are the rule but these are confined to the lower extremities The most constant of these produces the char acteristic pes cavus Moderate wasting of the small muscles of the feet and hands is not very uncommon Sensibility is but little affected but in most cases minute examination reveals slight relative loss to touch pain and temperature most marked at the periphery of the limbs and diminishing upwards Similarly there may be slight loss of sense of position in the limbs and diminished vibration sense

The ocular movements are almost always intact apart from the already described nystagmus In rare instances strabismus diplopia and ptosis have been recorded The pupils are not affected Optic atrophy is a rare phenomenon in Friedreich s disease yet it has been reported in quite a number of otherwise typical cases

Mental symptoms are usually not conspicuous but some of the patients are of poor mentality from the first while others show a tendency to severe mental degenera tion in the later stages of the disease Emotional instability irritability and outbursts of temper may occur

Absence of the tendon reflexes is a most characteristic feature and is often the

spot in the region of the macula and in addition optic atrophy occurs later and (4) a fatal termination in the marasmic state before the age of 2 years

Ætiology —Nothing is known of the ætiology of the disease apart from its familial and racial incidence The tendency to the disease is unquestionably congenitally installed

Pathology —This is very striking It consists of a progressive degeneration of the nerve cells from the highest to the lowest and ultimately there may be no normal cells remaining anywhere in the nervous system The degeneration takes the form of swelling of the cell protoplasm and of the dendrites with chromatolysis swelling of the hyaloplasm and destruction of the cell fibrils followed by disappearance of the nucleus and finally by absorption of the remains of the cell The degenerating nerve cells are characterised by the accumulation of granules of lipoid substances which resemble those observed in other cells of the body in Gaucher s disease Niemann-Pick s disease and the Hand Schuller Christian disease Every cell of the central nervous system both of the brain spinal cord and spinal ganglia is in the end similarly affected

Symptoms —There are few diseases in which the *clinical manifestations* are so perfectly uniform as in this malady The children have all been born at full term and in perfect health They thrive well during the first 3 to 6 months of life when *they gradually become listless and apathetic cease to take interest in the surroundings* and begin to show signs of the visual failure which ends in blindness Later the child is unable to sit up or to hold up its head The limbs which may be slightly spastic at first become flaccid and motionless There is a gradual increase of all these signs The mental defect becomes more and more noticeable the paralysis more extreme complete blindness follows and the patient sinks into a condition of marasmus in which he dies Convulsions nystagmus and strabismus are sometimes present

The retinal changes are pathognomonic and are due to a degeneration and dis appearance of the nerve cells of the retina and their processes which constitute the fibres of the optic nerve This change is most intense in the region of the fovea centralis where the retina thins and disappears over a circular area exposing the vascular choroid This gives rise to the characteristic appearance on ophthalmoscopic examination of a cherry red spot in the region of the macula This spot is actually a hole in the retina exposing the choroid The optic disk shows progressive atrophy

Diagnosis —Distinction has to be made between this and other forms of pro gressive diplegia The symptoms are so distinct that a physician who is acquainted with the disease and able to recognise the retinal picture can hardly fail to make the correct diagnosis

Treatment —No treatment is of any avail

2 OTHER FORMS OF CEREBRO MACULAR DEGENERATION

In addition to the classical infantile form described in the preceding article two other forms are well known in which the pathological changes are similar but much less severe than in the Warren Tay Sachs disease and there is also a similar familial incidence but the onset of the malady occurs later in life and the course is less rapid and the result far less serious The later the onset in life the slighter and less progressive are the symptoms The cherry red spot at the macula so constant in the infantile form does not occur in the later forms The characteristic retinal change is a disturbance of the retinal pigment commencing in the macular region rather like retinitis pigmentosa accompanied by honeycomb changes at the macula and sometimes by optic atrophy The *juvenile* form occurs in later childhood and is characterised by the association of the retinal changes and visual defect with some degree of mental deterioration The *adult* form is the least progressive of any and the clinical

Diagnosis —With the foregoing features it is natural that the disease should frequently be mistaken clinically for disseminated sclerosis The later age incidence the absence of nystagmus of disk changes of spasticity and of loss of sense of position and the steady progress of the malady should make the diagnosis of disseminated sclerosis untenable while the reeling character of the ataxia and the sibilant instead of staccato quality in the articulation disclose the real nature of the disease In tabes dorsalis, with which it may be confused because of the ataxia numerous characteristic signs are present by the time ataxia becomes pronounced, and dysarthria is not a feature of tabes

Treatment —No treatment is known to have any effect on the degenerative process

3 FAMILIAL SPASTIC PARALYSIS

Ætiology —This rare disease is sometimes hereditary but is more commonly familial and incident upon several children of the same parents Sporadic cases also occur The onset is gradual in early life, and usually occurs after the sixth year

Pathology —The pathological changes consist in a primary degeneration of the pyramidal neurones which apparently takes place in terms of the length those supplying the lumbo sacral region being lower and longer are earliest affected those supplying the brain stem being shortest are the last to be affected Degenerative changes in the neurones of the posterior columns of the spinal cord are often present *showing the transition to the pathological type of the hereditary ataxies*

Symptoms —The clinical aspect consists in the slow development of spasticity and weakness first and most in the legs which gradually increases and progresses to the trunk and upper extremities and involves the face last and least The usual signs of pyramidal involvement are present in the loss of abdominal reflexes increased deep reflexes and extensor type of plantar reflex The malady is progressive increasing to complete paralysis and in its course contractures of the spastic muscles occur that of the foot and leg producing some degree of pes cavus while, above this flexor contracture at hip and knee is met with Optic atrophy is by no means uncommon Mental symptoms do not occur in uncomplicated cases neither is epilepsy observed

Diagnosis —This malady is most easily confused with cerebral diplegia but the latter disease appears much earlier as soon after birth in fact as defective movement in the child can be ascertained Further cerebral diplegia is not a progressive disease in the majority of the cases and *it is often associated with mental deficiency* and recurring convulsions

Treatment —This is the same as that of Friedreich s ataxia except that the purpose of exercises if given should be to secure the best use of the spastic lower limbs *instead of to overcome ataxia*

4 CEREBRO MACULAR DEGENERATION

1 THE INFANTILE FORM

Synonyms —Warren Tay Sachs Disease Amaurotic Family Idiocy

Definition —A family disease of infancy occurring chiefly but not entirely in the Hebrew race *affecting children during the first year of life* who are apparently quite healthy when born and characterised by—(1) progressive mental impairment ending in absolute idiocy (2) progressive paralysis of the whole body (3) progressive diminution in sight, ending in absolute blindness *Pathognomonic retinal* changes are constantly present consisting of a large and conspicuous cherry red

spot in the region of the macula and in addition optic atrophy occurs later and (4) a fatal termination in the marasmic state before the age of 2 years

Ætiology—Nothing is known of the ætiology of the disease apart from its familial and racial incidence The tendency to the disease is unquestionably congenitally installed

Pathology—This is very striking It consists of a progressive degeneration of the nerve cells from the highest to the lowest and ultimately there may be no normal cells remaining anywhere in the nervous system The degeneration takes the form of swelling of the cell protoplasm and of the dendrites with chromatolysis swelling of the hyaloplasm and destruction of the cell fibrils followed by disappearance of the nucleus and finally by absorption of the remains of the cell The degenerating nerve cells are characterised by the accumulation of granules of lipoid substances which resemble those observed in other cells of the body in Gaucher s disease Niemann-Pick s disease and the Hand Schuller Christian disease Every cell of the central nervous system both of the brain spinal cord and spinal ganglia is in the end similarly affected

Symptoms—There are few diseases in which the *clinical manifestations* are so perfectly uniform as in this malady The children have all been born at full term and in perfect health They thrive well during the first 3 to 6 months of life when they gradually become listless and apathetic cease to take interest in the surroundings and begin to show signs of the visual failure which ends in blindness Later the child is unable to sit up or to hold up its head The limbs which may be slightly spastic at first become flaccid and motionless There is a gradual increase of all these signs The mental defect becomes more and more noticeable the paralysis more extreme complete blindness follows and the patient sinks into a condition of marasmus in which he dies Convulsions nystagmus and strabismus are sometimes present

The retinal changes are pathognomonic and are due to a degeneration and disappearance of the nerve cells of the retina and their processes which constitute the fibres of the optic nerve This change is most intense in the region of the fovea centralis where the retina thins and disappears over a circular area exposing the vascular choroid This gives rise to the characteristic appearance on ophthalmoscopic examination of a cherry red spot in the region of the macula This spot is actually a hole in the retina exposing the choroid The optic disk shows progressive atrophy

Diagnosis—Distinction has to be made between this and other forms of progressive diplegia The symptoms are so distinct that a physician who is acquainted with the disease and able to recognise the retinal picture can hardly fail to make the correct diagnosis

Treatment.—No treatment is of any avail

2 OTHER FORMS OF CEREBRO MACULAR DEGENERATION

In addition to the classical infantile form described in the preceding article two other forms are well known in which the pathological changes are similar but much less severe than in the Warren Tay Sachs disease and there is also a similar familial incidence but the onset of the malady occurs later in life and the course is less rapid and the result far less serious The later the onset in life the slighter and less progressive are the symptoms The cherry red spot at the macula so constant in the infantile form does not occur in the later forms The characteristic retinal change is a disturbance of the retinal pigment commencing in the macular region rather like retinitis pigmentosa accompanied by honeycomb changes at the macula and sometimes by optic atrophy The *juvenile* form occurs in later childhood and is characterised by the association of the retinal changes and visual defect with some degree of mental deterioration The *adult* form is the least progressive of any and the clinical

manifestations are the visual defect and retinal changes in the absence of mental deterioration

5 HEPATO LENTICULAR DEGENERATION

Synonyms —Progressive Lenticular Degeneration Wilson s Disease

Definition —A rare progressive disease of the nervous system often familial characterised by involuntary movements rigidity and hypertonicity, with contractures without signs of pyramidal disease and by dysarthria dysphagia emotionalism and progressive *emaciation* Several closely related clinical forms of the disease bear distinctive names *tetanoid chorea* (Gowers) *pseudosclerosis* (Westphal) *progressive lenticular degeneration* (Wilson) and *torsion spasm* and *dystonia musculorum deformans* (Thomalla) Cirrhosis of the liver occurs in all forms The Kayser Fleischer zone of corneal pigmentation occurs in the first three forms but has not yet been recorded *in torsion spasm* The most constant nervous lesions are found in the corpus striatum

Ætiology —The disease often occurs in children of the same parents but there is no evidence that it is congenital or hereditary The age of onset has been as early as 7 years and as late as 26 years The primary and essential lesion is in the liver, its cause is unknown Syphilis is not a factor

Pathology —A *multilobular* cirrhosis with 'hobnail' liver is always found after death There is good evidence that the cirrhosis is not slowly progressive but is the result of a number of attacks of acute hepatitis The hepatitis has caused death in some members of affected families before nervous symptoms appeared The nervous lesions are purely degenerative In Wilson s cases they were almost confined *to the lenticular nucleus especially the putamen Every degree of degeneration* was seen from discoloration and sponginess of the nucleus in rapidly fatal cases to shrinkage and atrophy and even to complete disintegration and excavation of the ganglion Later observers have described lesions in many other parts of the nervous system The lesions are often most intense in the corpus striatum but the noxious agent has *no strictly selective action on any one anatomical group of ganglion cells or on any* limited area of the nervous system It is now known that the degenerate basal ganglia contain excessive amounts of copper compounds and that there is a persistent excess of this element in the urine as well as an increased urinary excretion of amino acids

Symptoms —In many cases there are no symptoms of disorder of the liver during *life In other cases an account is obtained of symptoms referable to acute hepatitis* before the onset of nervous symptoms—attacks of diarrhœa and vomiting pyrexia jaundice migrainous headaches hæmatemesis and sometimes definite ascites

The first nervous sign to appear is usually involuntary movement of the extremities which may be of several kinds In progressive lenticular degeneration rhythmical tremors increasing on voluntary movement furnish the most common symptom This is followed by rigidity of the face the muscles of the neck and later of the trunk which rigidity *increases steadily until the patient becomes helpless* The rigidity of the face and neck muscles gives rise to a peculiar expressionless appearance *Still* later extensive contractures usually in the flexed position in the upper and lower extremities follow but sometimes there is extensor contracture of the latter During sleep the tremors cease but the contractures do not relax Dysarthria of a slurring type, *results from affection of the muscles of speech* and may end in complete anarthria Progressive muscular weakness and general emaciation follow and the patient becomes emotional *facile docile and childish There is no* fibrillation or localised amyotrophy The optic disks and pupillary reactions are normal There is an absence of nystagmus cerebellar symptoms and impairment of *sensation* The reflexes are not altered as in the case in pyramidal disease

Prognosis —The disease always ends fatally in a few months or years the *average duration is about 4 years*

Treatment—No curative treatment is known but there is evidence that symptoms are improved and the progress of the disorder delayed by treatment with dimercaprol (British Anti Lewisite)

6 KERNICTERUS

Definition and Ætiology—A yellow pigmentation of certain of the basal ganglia associated clinically with motor disorders of the type known as extra pyramidal and found as a rare phenomenon in children who normal at birth develop jaundice within the first 3 days of life

In neonatal jaundice the brain may be diffusely pigmented or more rarely the pigmentation may be confined to the putamen subthalamic and dentate nuclei the cornu Ammonis and fascia dentata To the latter variety of jaundice of the brain the name kernicterus has been given by Schmorl The nerve cells in the affected masses of grey matter show evidence of destruction and degeneration while the nerve fibres are demyelinated

Symptoms—The child is healthy at birth but within a few days develops intense jaundice usually the form known as hæmolytic disease of the new born (see p 745) and now known to be due to Rhesus incompatibility between the parents though kernicterus has been found in association with septic jaundice The onset of jaundice is followed within 24 hours by tonic and clonic movements muscular rigidity and opisthotonos alternating with periods of flaccidity If the child survives involuntary movements of choreoathetoid form develop within a few weeks Emotional instability and mental retardation appear as the child grows older

Diagnosis—Athetosis and comparable forms of involuntary movement are not rarely seen in children and are in the majority of instances not associated with kernicterus Yet when a case of such motor disorder is seen in a child in respect of whom there is a history of neonatal jaundice the possibility of this disease should be borne in mind Again the development of marked symptoms of organic nervous disease immediately after the appearance of severe jaundice in a newly born infant should lead to a consideration of this condition as the probable pathological basis

Prognosis—There is a marked tendency for these patients to die during infancy or childhood of intercurrent disease but a minority survive to adult life with a varying degree of mental impairment and disorder of movement

Treatment—There is no curative treatment and endeavour should be directed towards education and towards training in co ordinated movements In cases where sufficient intelligence exists much can be done by patient training especially in the hands of trained workers

7 NEUROFIBROMATOSIS

Synonym—Von Recklinghausen s Disease

Definition—A complex disorder involving principally the skin and nervous system and characterised in the former by the development of abnormal pigmentation and a great variety of tumours and in the latter by the presence of multiple neurofibromata in the peripheral and less frequently the central nervous system

Ætiology—The disease is both hereditary and familial though isolated cases occur Formes frustes are common Although the characteristic features evolve during the life of the patient the malady undoubtedly results from congenital abnormality It is often associated with other congenital and developmental anomalies of the nervous system and skeleton and subjects of the disease show a remarkable propensity for neoplastic disorders

Pathology —The cutaneous lesions comprise fibromata many of which are degenerate nævi and areas of pigmentation In the nervous system multiple fibromata occur in the peripheral and cranial nerves and in addition meningeal tumours and gliomata of the brain and spinal cord may be found

Symptoms —Of the essential features of the disease the cutaneous lesions are usually the first to make their appearance Some may be present at birth others develop during childhood, adolescence or adult life They present a great variety of forms Abnormal areas of pigmentation are commonest These have the appearance of *cafe-au lait* patches and vary in size from a mere freckle to a large zone involving a whole limb Many are between the sizes of a sixpence and a shilling The cutaneous *tumours appear* gradually Some are pedunculated or sessile fibromata often pigmented and usually soft to the touch Others are nævoid in composition They may attain great size coming to form the large redundant folds of tissue known as *plexiform neuromata* The fully developed cutaneous picture is that known as molluscum fibrosum

The tumours on the nerve trunks are also fibromata but usually firmer than these in the skin They may occur on any of the peripheral nerves the limb plexuses or the intra pinal portions of the nerve roots Those peripherally situated are usually painless and seldom interfere with the function of the nerve on which they grow They are occasionally painful on pressure Those which originate on the spinal nerve roots produce the picture of spinal compression commonly preceded by a long period of root pain They are frequently multiple Within the cranial cavity neurofibromata are most often met with on the acoustic nerves but may occur on any of the cranial nerves and produce symptoms characteristic of their position

Von Recklinghausen s disease is often found in association with other congenital anomalies such as spina bifida meningocele cervical rib syringomyelia mental deficiency and epilepsy

The tumours are liable to undergo malignant degeneration and it is not uncommon to find other tumours, such as meningiomata and gliomata in patients with this disorder

Course and Prognosis —In many cases the condition is compatible with a long and relatively normal life though there is a tendency towards slow progression Danger to life results only from central lesions in the cranial or spinal cavities or from the rare malignant degeneration in the peripheral tumours

Treatment —Nothing is known to modify the natural course of the disease Central tumours should be removed surgically as they arise and cosmetic improvement can often be achieved for the cutaneous and subcutaneous lesions

8 TUBEROSE SCLEROSIS

Synonyms —Adenoma Sebaceum Epiloi

Definition —A condition characterised clinically by the symptom triad of multiple cutaneous tumours of the cheeks and face mental deficiency and epilepsy and pathologically by the presence in the brain of areas of gliosis of a peculiar type

Ætiology —Hereditary and familial incidence is common but many i olated cases occur No other factors are known The sexes are equally affected

Pathology —The characteristic lesions of the brain consist of nodular tuberous masses which are most plentiful under the ependyma of the ventricles into the cavities of which they project like candle gutterings Similar nodules can be seen and felt scattered throughout the cortex and rarely in the cerebellum or spinal cord They consist of dense tangles of neuroglia cells many of markedly pathological type The cutaneous tumours consist of an overgrowth of the sebaceous glands embedded

in nævoid and fibrous tissue Tumours also occur in other tissues namely rhabdo myomas in the heart and kidneys and the so called phakoma in the retina

Symptoms —These usually make their appearance in early childhood Varying degrees of mental defect from feeble mindedness to idiocy are universal Epilepsy usually begins within the first few years of life and though any form may occur generalised convulsion is the commonest The characteristic skin lesions make their appearance during childhood in the form of numerous verrucose shotty papules on the butterfly area of the cheeks and nose These are red or reddish brown in colour and the intervening skin is red and shiny The extent and degree of this condition of sebaceous adenoma becomes more marked as the child grows older Numerous other cutaneous tumours and congenital anomalies similar to these occurring in Von Recklinghausen s disease are met with

Course and Prognosis —The course is very slowly progressive Most cases spend their lives in institutions for mental defectives but frequently attain a considerable age

Treatment —Symptomatic treatment is indicated for the epilepsy and when possible procreation should be vetoed and the patient cared for in a suitable institution

CEREBRAL DIPLEGIA

Synonyms —Congenital Spastic Paralysis Lobar Atrophic Sclerosis

Definition —A group of clinical conditions dependent upon lack of or imperfect development or degeneration of the nerve cells of the cerebral cortex basal ganglia or cerebellum This agenesia of nerve cells may affect those cells of the pyramidal system which are the latest to develop before birth namely those for the supply of the lower extremities and the resulting clinical condition is cerebral spastic paraplegia or Little s disease or all the cells of the pyramidal system may be affected producing generalised spastic rigidity Again the higher regions of the cortex may be affected and the result is congenital idiocy Similar affections of the cells of the basal ganglia result in congenital bilateral athetosis and congenital chorea When the cerebellum is involved congenital cerebellar ataxy results Further there may be any combination of the above conditions

Ætiology —The malady may be apparent at the time of birth as the child may be born with contractures present More often the signs of deficient or perverse movement or of mental deficiency appear during the first year of life as the signs of cerebral activity commence to be exteriorised In most cases no heredity can be traced but sometimes several children of the same mother may be affected and direct heredity has been known

Abnormalities of birth are frequent Premature or precipitate birth prolonged birth from uterine inertia rather than from dystocia and asphyxia neonatorum are all common The child is frequently the first born of its mother

Collier has expressed the probable pathogenesis of cerebral diplegia as follows If we regard the brain from the time of its earliest stages of development as a field sown with seeds (neuroblasts) which germinate at different periods of fœtal life and the germination is not even complete at the time of birth the germination of all the elements in due time and their complete development being neces ary for the formation of the perfect brain then we may liken the cause of diplegia to some baneful influence such as a frost which acting at a particular time may spare those seedlings which are well developed and able to withstand it and those seeds as yet not germinated but which causes havoc among the tender germinating seedlings either to their death or severe maiming In some cases as for example in Little s disease the neuroblasts thus affected may after a period of retarded development ultimately become strong plants and complete their development It is of interest that in the

highest degrees of cerebral agenesia—anencephaly, pituitary abnormalities seem to be constant

A well defined variety of cerebral diplegia associated with congenital deafness is now known to occur as a result of the mother suffering from rubella in the early months of pregnancy

Pathology —The essential histology of the affected regions is that of non development paucity in numbers and degeneration of the nerve cells with corresponding absence poor development degeneration or a combination of these states of the tracts which spring therefrom The pyramidal tract, for example, may be found absent throughout, or it may reach to the medulla, or to the cervical region only and so show at what period development was arrested The changes in the nerve cells are followed by secondary gliosis The final result is termed atrophic sclerosis More often certain regions are profoundly affected, while others escape relatively or completely, but the distribution is always symmetrical upon the two hemispheres The convolutions are unduly hard to the touch and their surfaces often present a worm eaten and faceted appearance This irregular form of the convolutions with wide, separating sulci, gives the brain a characteristic appearance, like that of a walnut kernel

Symptoms —The clinical picture of the several forms of cerebral diplegia presents a combination in varying degrees of certain characteristic symptoms always bilaterally distributed though sometimes more severe on one side than on the other These symptoms are muscular rigidity paresis perverse movements contractures and increased deep reflexes Mental deficiency optic atrophy and ataxy are other important symptoms The signs of the disease become obvious during the first year of life or soon after In severe cases soon after birth the nurse in washing the child is the first to notice the stiffness of the limbs or the regular assumption of a curious bodily attitude Otherwise the abnormalities may not be obtrusive until the child should sit up or learn to get about, when weakness rigidity perverse movements and pes cavus may call attention or backwardness in learning to walk and to talk, and mental deficiency may first suggest that there is something wrong with the child The following are the common types of the disease but it must be remembered that any combination of or transition between the types may be met with

1 *Generalised rigidity general congenital spastic paralysis* —There is extensive defect of the pyramidal system The rigidity and weakness affect the whole of the musculature

2 *Paraplegic rigidity congenital spastic paraplegia Little s disease* —The pyramidal deficiency is confined to that supplying the lower part of the trunk and lower limbs

3 *Congenital bilateral athetosis and congenital chorea* —The agenesia affects the cells of the basal ganglia with the appearance of irregularity of movement and of spontaneous involuntary movements which may be of an athetotic choreic or irregular type A certain variable degree of general rigidity is present in these cases

4 *Congenital cerebellar ataxy* —The agenesia affects the cerebellum with the appearance of cerebellar ataxy In this type the limbs are flaccid and in mixed cerebral and cerebellar types there is a tendency to hypotonicity of the muscles instead of rigidity

5 *Congenital idiocy restless idiocy* —The agenesia affects those parts of the brain concerned with the higher functions These children are emotionless restless and unteachable The skull often shows frontal or occipital microcephaly

6 *Microcephalic idiocy*—where the agenesia is of the whole brain and the skull remains very small

Paresis and Rigidity —Except in severe cases in which the weakness amounts to complete paralysis there is more rigidity than weakness and it is often astonishing that there should be so much power in the presence of such a degree of rigidity

The lower extremities are generally the most affected the upper to a less degree and the facial region still less Movement is slow and clumsy and spontaneous involuntary movements are often present in the limbs Contractures accompany the rigidity, and if walking is possible the gait is digitigrade from contraction of the calf muscles, the knees are flexed from contracture of the hamstrings the thighs are rotated inwards and the knees pressed together rubbing against one another More severe adductor spasm gives rise to the cross legged progression The rigidity and contractures when severe may give rise to peculiar attitudes and deformities A mask like expression of face with wide palpebral apertures and large open mouth is not infrequent Slobbering is very common The head may be rigidly retracted but more commonly the chin is pressed down upon the chest The spinal column generally shows some deformity in the way of kyphosis lordosis or scoliosis and pes cavus or equino varus is the rule

PERVERSE MOVEMENTS —Under this heading must be grouped the very constant maladroitness of voluntary movement the facial over action and grimacing in speech and in mimetic expression choreic movements athetotic movements and intention tremor Common sensation and the muscular sense are unimpaired The sphincters are unaffected The deep reflexes are increased but are often difficult to obtain when rigidity is very marked The trunk reflexes are often absent the plantar reflexes usually are extensor in type Since the growth of the skull follows and conforms with that of the brain cranial abnormalities are common There may be microcephaly asymmetry and flattening in the region of the central convolutions or a furrow corre sponding with the interhemispheric fissure or frontal or occipital smallness and flattening Every degree of mental reduction may be met with from slight mental dullness to complete amentia But this by no means corresponds with the severity of the bodily symptoms for the mental defect is often most severe when the bodily symptoms are slight and conversely In some cases very high intelligence persists when there is utter uselessness of the limbs and when speech is hardly intelligible Primary optic atrophy occurs in a small number of cases Inequality of the pupils and slowness of light reaction are not uncommon Nystagmus is often met with Convergent strabismus occurs in about one third of the cases Convulsive attacks are of common occurrence and in about one eighth of the cases epilepsy becomes established

Diagnosis —When the symptoms are well marked the diagnosis presents little difficulty since the disease dates mostly from birth or is discovered during the first year of life Paraplegic rigidity may possibly be confused with other forms of para plegia and especially with that resulting from spinal caries Certain cases of pontine tumour may closely resemble generalised rigidity The occurrence of such conditions during the first 2 years of life is however very rare

Prognosis —In many cases of generalised rigidity and in all cases of paraplegic rigidity there is a tendency to slow amelioration of the rigidity an increase of volun tary power and control of the muscles in the course of time especially under the in fluence of careful training and in paraplegic rigidity if the mental acuity be not seriously impaired laborious treatment may result in an almost normal condition of the limbs by the age of puberty On the other hand some cases of generalised rigidity become progressively worse and succumb usually before the end of the fourth year Bilateral athetosis and choreic diplegia as a rule follow a very slowly progressive course without tendency to a fatal result Paraplegic rigidity apart a great many of the cases of all forms of diplegia succumb before the sixth year and in those who survive this age the tenure of life is short few reaching far into the third decade of life

Treatment —In those cases with a marked degree of mental impairment and in those which show a course of progressive degeneration no treatment is of avail In slighter cases of generalised rigidity and in paraplegic rigidity treatment is to be

directed to the prevention of contractures to regaining of voluntary control and the improvement of mental acuity There is perhaps no disease which demands greater patience and persistency in carrying out of suitable treatment and there are few diseases in which more brilliant results may be produced from apparently hopeless cases by pertinacity in treatment It is in the early years when treatment is for the most neglected that good results are more quickly and readily obtained From the first regular massage and passive movements should be employed Voluntary movement should be encouraged as far as possible and as power and movement increase gymnastic exercises of every kind should be employed Rigid apparatus for prevention of deformity and to reduce contracture is harmful for it increases the weight of the limb and interferes with movement, which is the remedy with which paralysis is to be combated Tenotomy is of great service in the relief of deformity and contracture and should be soon followed by passive movements It should never be performed unless a fair degree of voluntary power is present Many of the patients seem to improve more rapidly if thyroid be administered in moderate daily doses

INFANTILE HEMIPLEGIA

While in childhood hemiplegia of slow onset is due to the same causes as in adults cerebral tumour being the common cause yet the majority of the cases of infantile hemiplegia of rapid onset are examples of diseases peculiar to children to which no comparable disease occurs in adults and to such cases the term infantile hemiplegia is restricted These conditions are due to gross organic lesions of the brain and for this reason must be strictly separated from the cerebral diplegias which are the result of cell lesions and not of gross lesions

Ætiology—In two thirds of all the cases the onset occurs within the first 3 years of life The malady becomes increasingly rare as childhood advances A few of the cases are of prenatal origin and a few are due to syphilitic fœtal vascular disease Again a very few cases are due to obstetrical events during birth by which the cerebrum is injured Acute infective diseases play a very important role in the causation of the disease for about one third of all the cases develop the malady during the course of a known infection By far the most important of such fevers are measles and scarlet fever but hemiplegia may occur in the course of pertussis small pox rubella diphtheria dysentery pneumonia typhus typhoid mumps malaria chorea and endocarditis While there can be no doubt that primary vascular lesions are responsible for many of the cases in which this condition complicates the specific fevers (whooping cough for example may cause cerebral hæmorrhage marasmic conditions in any fever may cause thrombosis of cortical veins and chorea and endocarditis may cause embolism) yet in some cases an inflammatory lesion of the brain or encephalitis is present

Pathology—The following lesions are met with either alone or combined in order of frequency (1) Atrophic sclerosis (2) cyst formation (3) shrunken patches resembling wet wash leather with some degree of atrophic sclerosis in their vicinity and (4) porencephaly The general appearance of these lesions which appear to be varying degrees of the same process suggests the end result of a vascular disturbance usually confined to the area of distribution of the middle cerebral artery There is evidence that many of them result from cerebral embolism occurring immediately after birth in association with the closing of the ductus arteriosus

Symptoms—The onset is rapid and in two thirds of all the cases the disease is ushered in by convulsions which may be unilateral but are more frequently general and are frequently repeated during a period of from a few hours to 24 hours after which the patient sinks into a subconscious state from which he gradually emerges in the course of a few days to show the signs of some cerebral defect usually hemi-

plegia sometimes hemianopia or aphasia or any other sign of local cerebral or cerebellar lesion Pyrexia often accompanies the convulsion and vomiting is common The onset may be without convulsions or loss of consciousness

The relation of the onset of the paralysis to the convulsion varies It may reach its height immediately after the initial convulsion or slight hemiparesis may occur which deepens after each subsequent convulsion Sometimes the early convulsions leave no paralysis but this appears towards the end of the first week either suddenly with fresh convulsion or gradually as the patient recovers from the comatose state The paralysis at its onset is flaccid and involves the whole of one side of the body to a greater or smaller extent An initial monoplegia is of extreme rarity The paralysis may not reach the greatest intensity until the end of the second week Subsequently it lessens in some cases disappearing completely in from a few weeks to 3 months in others it may show no sign of improvement The limbs at first flaccid subsequently become spastic and develop contractures In the course of years there may be great arrest of growth on the affected side and this is not necessarily proportional to the degree of paralysis but apparently depends upon the degree of destruction which has occurred in the parietal lobule Post hemiplegic spontaneous movements of an athetoid choreic or irregular kind are common and are attributable to lesions in the corpus striatum and subthalamic grey matter for which regions encephalitis shows an especial predilection Epileptic fits recur at varying intervals in about half of all cases of infantile hemiplegia These always commence upon the affected side and are sometimes confined to it Mental deficiency is met with in all degrees in relation to the position and extent of the cerebral cortex which is involved in the lesion

Diagnosis—The nature of the malady at the onset with convulsions may possibly be suggested by prodromal pyrexia by the severity and long duration of the convulsions and by the prolonged subconscious state that often follows Convulsions occurring several days after the onset of specific fevers should strongly suggest *the diagnosis When the signs of hemiplegia or of other local cerebral lesions appear* the diagnosis presents no difficulty

Course and Prognosis—In a very small proportion of the cases the patient does not survive the initial manifestations of the disease and dies in convulsions Apart from this event infantile hemiplegia has little tendency to destroy life The initial flaccid hemiplegia tends to improve and gives place to a slowly improving spastic hemiplegia which with the return of some power shows perversity of movement stiffness and slowness ataxy athetosis and choreic movements or tremors according to the position of the lesion The spontaneous movements appear within a year of the onset Slow improvement may go on for years but cases with much mental reduction or in which recurring epilepsy is frequent improve but little

Treatment—We know of no measures that avail to prevent the occurrence or lessen the severity of the cerebral destruction which occurs in these cases Too often the damage to the brain has happened as soon as a diagnosis is possible When the paralysis has developed treatment is to be directed to the prevention of rigidity and contractures by regular passive movements to regaining voluntary control by encouragement and patient exercises and to the improvement of mental acuity Where there is much contracture and deformity tenotomies are of great service provided there be some voluntary power in the muscles the tendons of which are to be divided Recurring convulsions should be treated as idiopathic epilepsy

Severe cases of this disorder as they reach childhood and adolescence present a very characteristic picture The infantile hemiplegia is associated with some degree of failure of growth in the affected limbs and with perverse movements In addition epileptic fits mental retardation and violent temper tantrums are characteristic

Such cases have of recent years been increasingly treated by complete surgical removal of the damaged hemisphere This hemispherectomy is usually followed

not only by cessation or improvement in the fits but by a marked improvement in the mental enfeeblement and the temper tantrums Even more surprisingly the *severity of the hemiplegia instead of being increased is diminished*

PAROXYSMAL DISORDERS OF THE CENTRAL NERVOUS SYSTEM

EPILEPSY

INTRODUCTION —Epilepsy in the widest sense may be defined as a persistent liability to occasional seizures The seizures may be associated with organic disease of the brain or a toxic state and if so the epilepsy is said to be symptomatic If the attacks are of such a nature that they point to a focal lesion of the brain (see p 1497) and particularly if consciousness is retained during the whole or a considerable part of the seizure the term Jacksonian epilepsy is applied to them More commonly there is no discoverable organic disease of the brain and no toxic state (*e g* uræmia eclampsia) with which fits are known to be associated and the epilepsy is then described as idiopathic or essential It is becoming more and more common to restrict the use of the general term epilepsy to this last variety, but it is apparent that the clinical division of the cases of epilepsy into symptomatic and idiopathic cannot be absolute if only for the reason that organic cerebral disease may not declare *itself except by the occurrence of fits In the absence of other indications of cerebral* disease there is no positive feature by which either variety can be recognised

SYMPTOMATIC EPILEPSY

The known causes of symptomatic epilepsy are numerous In addition the diagnosis is often based on assumption because some item in the history of the case provides a basis for supposing that organic cerebral disease or injury has occurred and it requires much knowledge and good judgement to assess whether such an assumption is well founded Injury of the brain of any nature whatever whether from violence from without or from disease within may cause epilepsy Cerebral tumours agenesia encephalitis meningitis cerebral syphilis abscess and certain types of vascular lesions give a high percentage of epileptic sequelæ or accompaniment Another cause of symptomatic epilepsy that should be borne in mind when a previously normal person who has lived abroad develops fits is cysticercosis of the brain Acute intoxications with lead alcohol absinthe and many other poisons may *evoke epileptiform fits as may also eclampsia uræmia hyperpiesis* cholæmia and the specific fevers of childhood and although in these conditions the epileptic phenomena do not usually recur after the intoxication has terminated nevertheless any one of them may be the apparent beginning of persistently recurring epilepsy

IDIOPATHIC EPILEPSY

Definition —A liability to fits or minor seizures prone *to recur over long periods* of time or even throughout life without any discoverable organic disease of the brain or other known cause of fits

The fit is a *disturbance of function due to a sudden* excessive and uncontrolled discharge of nervous centres and this is believed to be due to a disturbance of the metabolism of the cells in which the abnormal discharge originates Of the nature of this metabolic disturbance we are still ignorant and as far as we know it is not associ-

ated with any recognisable change in the histological appearances of the cells concerned The metabolism of nerve cells in activity is accompanied by changes of electric potential and under suitable circumstances the potential changes in the cerebral cortex can be recorded by the electro encephalogram Normally they are rhythmical alternations at the rate of 8 to 12 per second (the α rhythm) and the best records of them are obtained from the occipital region of the head when the patient closes his eyes and relaxes At the time of an epileptic fit there are repetitive excessive electric discharges all over the cortex and these are followed by a period of electrical inactivity lasting some minutes At the time of a *petit mal* attack the E E G shows a single spike indicating one excessive discharge occurring all over the cortex or a succession of spikes In many epileptic patients the electrical record indicates that intermittent abnormalities of the rhythm are present during the intervals between the

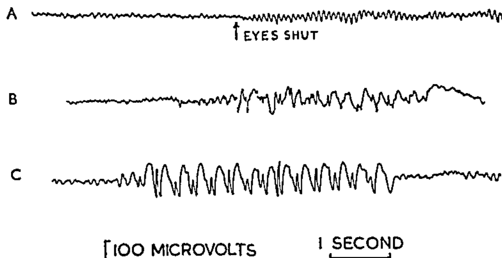

FIG 2 ELECTRO ENCEPHALOGRAMS

A Normal alpha rhythm largely absent with the eyes open and appearing when they are closed 11 cycles per second
B An episode of waves of mixed frequency in a case of idiopathic epilepsy
C An outburst of spike and wave complexes at 3 cycles per second accompanying a *petit mal* attack

By the kindness of Dr W A Cobb

fits and some of them are similar to those associated with a fit *i e* they are sub clinical attacks Abnormalities of the rhythm of potential variation are present in many other conditions besides epilepsy but when the complex known as the spike and wave appears on the record it is believed to be indicative of epilepsy Many epileptic patients however do not show this abnormality on their records and the records may either be quite normal or may show other non characteristic abnormalities Electrical abnormalities are found alike in idiopathic and in symptomatic epilepsy but in the former they are more constantly present and are in general more widely diffused over the cortex and more readily modified by such activities as over breathing

Ætiology—It is important to be clear in our minds what we mean by the cause of epilepsy In symptomatic epilepsy organic disease of the brain is usually present but in idiopathic epilepsy there is no organic disease with which the liability to fits can be associated moreover the same organic disease *e g* a glioma of one frontal

lobe may be associated with fits in one case and not in others It is thus evident that the organic disease is not the immediate cause of the liability to abnormal dis charges but it is a more remote cause Of the more immediate cause (or causes) of the liability to attacks almost nothing is known beyond the indications of metabolic disturbance in nerve cells that have already been referred to Of remote causes of the liability in addition to organic disease of the brain *heredity* is the most important. While this factor is regarded much less seriously now than formerly the fact remains that in a still considerable proportion of cases, a history of epilepsy in a near relative is obtained Moreover recent electro encephalographic observations by Lennox suggest that in the parents (one or both) of epileptic subjects abnormally wide fluctua tions in the rhythm of the brain potentials are unduly common and it may be that while epilepsy as such is not inherited some instability of cortical cell function may be inherited which in combination with other factors leads to the appearance of epilepsy under certain (as yet unknown) circumstances

In the vast majority of cases of idiopathic epilepsy the tendency to fits first reveals itself in childhood or adolescence In 70 per cent. of cases attacks have begun by the age of 20 and in 85 per cent by the age of 25 In a small number of cases idiopathic epilepsy first manifests itself in the fourth or fifth decade but far more frequently fits coming on after the age of 25 are symptomatic of organic cerebral disease Often children starting to have fits in adolescence have had convul sions in infancy

The frequency of fits in the same patient is subject to great variability so that the liability to abnormal discharge evidently fluctuates When it is sufficiently great, there must also be a final exciting cause which starts off the attack—especially the major fit Of the cause(s) of fluctuations in the liability to attacks and of the exciting causes of fits we are again quite ignorant The most that can be said is that some thing is known from empirical observation of the conditions in which fits often occur These are subject to great variability from patient to patient but often show great uniformity for the same individual

More than half of all (convulsive) attacks occur during sleep There are many individual patients whose attacks invariably occur during sleep and this is often called nocturnal epilepsy but the liability attaches to sleep whether nocturnal or diurnal and the Sunday afternoon nap in front of the fire is frequently productive of fits in such patients Of the nocturnal fits many occur soon after the patient has fallen asleep, but still more in the last few hours before waking There are some epileptics who never have fits except in sleep and in general the liability to fits during sleep is much greater than during the waking state The next greatest frequency of attacks attaches to the first hour or so after waking Many patients have their attacks usually or invariably when washing in the morning or dressing or about breakfast time, so much so that for the average patient the liability during this first waking hour seems considerably greater than for any other hour of the twenty four During the rest of the day the liability to attacks for the average patient is much less but this is not to say that many fits do not occur during the day and occur sometimes under the most unpredictable circumstances In general the patient seems less liable to attacks while intent on the day s activities than when inactive relaxed or lounging or dozing In the evening especially in the last hour before bedtime the average liability to fits is again increased and some patients usually have their attacks at this time but in general the evening liability is not nearly as great as that of the first morning hour

In women there is a pronounced increase of liability to fits in association with the menstrual period beginning about 5 days before the onset of menstruation and lasting till the end of 48 hours after its termination with its maximum in the 2 days preceding the menses In many women who are relatively mild cases of epilepsy the attacks occur only at such times

There is a popular idea that emotional excitement has an influence in precipitating fits in epileptic patients but it is rarely that the personal histories of patients provide any confirmatory evidence for this and the only emotion that seems to have any effect in increasing the liability to attacks is fear and even that is doubtful In a few patients concentration on studies has an adverse effect

Physical disturbances such as vertigo nausea vomiting seem also to increase the liability to fits as also does physical injury General anæsthetics often precipitate fits in epileptic subjects and an injection of novocain seems to increase the liability so that an attack may occur after some hours

The retention of water in the body brought about by the intake of a large amount of fluid and the injection of pituitrin subcutaneously leads to the occurrence of a fit in 50 per cent or more of susceptible subjects and this has been used as a diagnostic test for epilepsy but such a test is rarely called for if adequate attention is given to the description and circumstances of suspected fits

Symptoms —PRODROMATA —The circumstances which immediately precede the occurrence of an attack are of some importance As has been mentioned it is uncommon speaking generally for an attack to occur when the attention is fixed or when some act is being performed and from this it follows that the epileptic is relatively or absolutely free from attacks when at work and doing and only in rare cases comes to harm or injury from accident Some patients are able by effort of will in fixing attention or by the performance of some vigorous action to arrest attacks which threaten or have even begun

Sometimes a change in the general condition of the patient may make him aware or may acquaint those around him that an attack is pending and such signs of altered health may herald an attack for from a couple of hours to a week Headache irritability restlessness euphoria depression lethargy somnolence unusual appetite and a peculiar vacant look may all be met with in this connection

Not infrequently the attack is preceded by paroxysmal manifestations which are in reality minute attacks such as partial lapses in consciousness a sense of strangeness dreamy state jactitations of any of the muscles exactly resembling those seen in uræmia, slight auras giddiness sneezing and yawning

DESCRIPTION OF THE ATTACKS —The varieties of the epileptic attack are legion and several types may occur in the same subject—indeed it is unusual for fits to be always of the same type in one subject They tend to vary both in degree and nature They are usually divided into major attacks in which spasm is conspicuous and the less spectacular minor attacks in which spasm is not a prominent feature This distinction is purely artificial for most patients have attacks of both varieties and the two merge by insensible gradations the one into the other

The following description will serve to illustrate the more definite manifestation of epileptic attacks

GENERAL CONVULSIVE FITS (*haut* or *grand mal*) —There is some reason for believing that every major attack has a local commencement in some region of the brain and that it is in reality a local fit which rapidly becomes general When such an attack commences with a local aura there is proof positive of local commencement When it commences with conjugate deviation of head and eyes to one side this is a certain indication that the disturbance commences in the opposite hemisphere When the spread of the disturbance is so rapid as to cause instant loss of consciousness there is no memory to retain the initial event of the attack The seizure may begin with any of the local manifestations described later the epigastric aura and giddiness being two of the most frequent Or the patient may only be aware of his attacks from the condition in which he finds himself after their occurrence The tonic spasm commences with conjugate deviation of both eyes to one side followed by rotation of the head to the same side The blood pressure falls the countenance is for a moment pallid the eyes widely open the pupils dilated the corneæ insensitive The march

of the tonic spasm usually causes head retraction and opisthotonos the upper extremities are stiff in flexion and adduction the lower extremities in extension If standing the patient falls usually backwards but the conjugate deviation of head and eyes may bring his face to the ground first The respiratory muscles and larynx going into spasm produce the epileptic "cry" and the respiratory movements being no longer possible the face darkens with the asphyxia and the sphincters may relax with the evacuation of bowel or bladder The protrusor spasm of the tongue and the closing spasm of the jaw may cause the tongue to be bitten After the tonic spasm has lasted some seconds and perhaps has produced such a degree of asphyxia as seems hardly compatible with survival it begins to break into a series of sudden shock like, jerky movements—the clonic spasm—which continue for some seconds becoming less regular and occurring at longer intervals until with a final jerk the muscles become perfectly limp Meanwhile the relaxation of the respiratory and laryngeal spasm has allowed the respiratory movements to return and to churn up the saliva often bloodstained which escapes at the nose and mouth in the form of froth At the end of the attack there is complete and unrousable loss of consciousness, the pupils are dilated and insensitive to light the corneal reflexes absent the knee jerks absent and the plantar reflexes extensor in type In a short time the knee jerks return the plantar reflexes return to the normal and consciousness returns Usually the patient is dazed feels ill, has marked headache and if left to himself soon sleeps heavily for some hours It must be noted that the general convulsive attack almost always leaves the patient face downwards so that he has been known to drown in a puddle an inch deep and has been asphyxiated by his own pillow The latter event is by far the commonest way in which the epileptic meets his death from accident in a fit

The epileptic cry—There are two quite different sounds that may occur at the commencement of an epileptic attack The one is a natural conscious cry of terror at the advent as in the patient who alternated piercing screams with ' It is coming! It is coming! before the convulsion commenced It is curious how rarely any memory of such cries or utterances remains with the patient The other is the epileptic cry proper—a weird unearthly hollow sound produced by inspiratory spasm drawing air over the nearly closed vocal cords This cry occurs in a minority even of severe cases for the obvious reason that it is determined by a particular march of the spasm If the inspiratory spasm occurs before the larynx has gone into spasm or after it is in spasm there can be no laryngeal noise but only the commonly witnessed pharyngeal and buccal grunting and gurgling The spasm must be so timed that the inspiratory spasm must occur as the larynx is closing and this only obtains in a minority of the cases

Tongue biting—Some patients always bite the tongue others never and some now and again The tongue is always bitten at the side and some way from the tip because it is deviated to one side in the spasm and its thicker part brought between the molar teeth The same side is usually bitten The tongue cannot be bitten unless protrusor spasm occurs either before the jaw has gone into tonic spasm or after it has broken into clonic spasm If any other march of spasm occurs the tongue escapes It is remarkable how little scarring occurs even from severe and repeated tongue biting unless a piece is bitten clean out

Incontinence—Though common incontinence is by no means invariable even in severe attacks More often it is the urine alone that is evacuated much more seldom the bowel alone still more rarely both A rare phenomenon during an epileptic fit is seminal emission

Secondary events—The degree of asphyxia during the attack may be severe and blood vessels may give way under the stress with the production of surface ecchymoses or deep hæmorrhages including cerebral hæmorrhage The spasm is powerful and may give rise to much subsequent aching as if the patient had been beaten all

over It may dislocate joints rupture muscles and even break bones A dislocation once produced in a fit is very liable to recur with subsequent fits

Duration of epileptic attacks—Two minutes may be given as an outside time limit for the duration of an individual attack from its commencement to the end of the active phenomena and in convulsive attacks to the end of the spasm Usually the time is much shorter than this and often is a few seconds only Sometimes attacks are described as of much longer duration When analysed such attacks will be found to be a series of attacks with very short intervals or slight attacks with post epileptic functional spasm or hysterical attacks

Other varieties of convulsive disorder are commonly encountered either as heralds of a *grand mal* attack or as the sole expression of the epileptic disturbance

SIMPLE JACTITATION—Simple twitchings of individual muscles or groups of muscles occurring now in one part of the body now in another are seen in the majority of epileptics at some time or other They are conspicuous in the convulsions of childhood where they often constitute the chief clinical feature They are well known as the carphology or subsultus tendinium of uræmic and eclamptic attacks, and in the typhoid state They may be not infrequently noticed in the epileptic person when he is otherwise well and engaged perhaps in conversation or other occupation Gowers emphasised epileptic twitching as a prodroma of an oncoming severe attack but while in some instances this is undoubtedly true yet it frequently occurs when no attack follows It has been called epileptic myoclonus'

LOCAL FITS—First studied by Hughlings Jackson these events bear the name of Jacksonian epilepsy and this term has unfortunately become coupled with common errors that were no part of Jackson s teaching These are (1) that some local disease invariably underlies the Jacksonian fit and (2) that the Jacksonian fit necessarily consists of local motor convulsion Actually in many cases naked eye and micro scopic examination may fail to reveal any local lesion and none such may be present Also the Jacksonian fit may consist of phenomena involving any possible cortical function It may be added that local disease of the brain quite commonly evokes generalised fits indistinguishable from those of idiopathic epilepsy and conversely that the latter form of epilep y may express itself in the form of Jacksonian fits

In local convulsive attacks the common foci of onset are the angle of the mouth the thumb and index finger and the great toe but the spasm may occasionally begin elsewhere It rarely produces conjugate deviation of the eyes as a primary move ment but usually in association with and secondary to deviation of the head The convulsive movements may remain confined to their place of onset throughout the fit or may spread widely so as to involve a whole limb one half of the body or the entire musculature In fits involving the musculature of the right half of the face and tongue speech is usually lost during the attack and returns shortly after its cessation Spasm never affects the muscles of one eyeball alone but the spasm is in terms of conjugate deviation of both eyeballs in one direction The same rule applies when the neck is affected for the head is then either rotated to one side or extended or flexed on the chest With the other bilaterally associated muscles it is different for the tongue is affected on one side only as is also the face The onset is with tonic spasm which after a little while gives place to broken or clonic spasm becoming more and more intermittent and finally ceasing In some cases but by no means in all the convulsion leaves varying degrees of weakness in the affected muscles—Todd s paralysis or post epileptic paralysis—with transient signs of loss of function of the pyramidal system such as loss of trunk reflexes increase of jerks and extensor plantar reflexes

Epileptic spasm usually puts the hand in the position of extension at the inter phalangeal joints and flexion at the metacarpo phalangeal joints with flexion at wrist and elbow and adduction at the shoulder The feet are dropped and inturned with extension at the knee and hip Usually the trunk is in opisthotonos

The sequence of tonic spasm followed by clonic spasm, though usual in epilepsy is not invariable Purely tonic fits may occur with no clonic spasm the tonic spasm remitting suddenly Such fits are usually of slight severity and duration On the other hand the spasm may be clonic only The simple jactitation already described may be taken as a simple clonic fit Local fits especially of the face and of the hand may be purely clonic

Loss of consciousness in local fits—This seems to depend upon the extent of the cortex involved With narrowly confined fits there may be no evident impairment at all as in local convulsion of the face or hand or as in a patient who vividly described a slow visual fit as it was occurring When the fit spreads consciousness is usually impaired, and when lost, it is lost late in the fit For example it is usual for a convulsion which spreads to one half of the body to cause some impairment and if it involves both sides generally consciousness is always lost

LOCAL PARALYTIC FITS (*simple paralysis*)—This is the rarest of all forms of the epileptic attack It consists in a sudden inability relative or complete, to use a limb or one side of the body or the whole voluntary musculature, with no preceding convulsion There are the usual signs of cerebral paralysis—at first flaccidity with a tendency for the jerks to fail a few moments later increased jerks, with absent trunk reflexes and extensor plantar reflexes all of which signs soon disappear The attack may occur as an isolated phenomenon More often a slight ' minor " attack or a local sensory attack accompanies the onset of the paralysis Sometimes such an attack may result from local disease of the brain Such episodes when involving the right face or right side of the body may occasion aphasia, or the aphasia may occur alone as the attack of simple paralysis Such attacks of simple paralysis without convulsion are well known in uræmia hyperpiesia and general paralysis of the insane

SENSORY EPILEPTIC DISTURBANCES—Numerous sudden sensory disturbances may be met with in epilepsy They may be related to the organs of special sense to those of common sensibility or to those of visceral sensibility They may occur as isolated events and so constitute the whole epileptic attack Often however the disturbance of the cortex spreads widely, involving general convulsion and loss of consciousness but the initial phenomena are remembered by the patient as the ' warning of the attack and have from ancient times been termed auras when preceding general convulsion In reality they constitute an essential part of the attack as showing the region of the brain in which the disturbance starts and in every patient who has such warnings preceding his severe attacks the warnings occur at times by themselves without any such sequel

Visual fits—These may take the form of negative phenomena such as dimness of vision complete darkness or hemianopia or of positive effects such as flashes of light scintillating stars or balls of fire or of both together in the form of blindness with flashes of light In the last case they may closely resemble the visual phenomena of migraine and are not infrequently caused by a local lesion of the occipital region Complex visual hallucinations may occur

Auditory fits—The hallucinations of sound may be of any nature—hissing booming and elaborate musical sensations as of bells being common There is usually a sense of coincident deafness of far away hearing which passes off with or soon after the sound

Olfactory and gustatory fits—These hallucinations are always described as of ' flavour usually unpleasant Very often movements of the lips tongue and jaw or swallowing movements are present and the dreamy state referred to below may be associated From the location of the functions of smell and taste in the cortex of the uncinate gyri and from the common occurrence of fits of this character in lesions of these convolutions this type of fit is often referred to as the uncinate fit

Sensory fits—These hallucinations may have their seat of commencement in any part of the body They may remain local but more commonly they spread from the point of origin in terms of the local representations of the body in the cerebral cortex and usually from the periphery towards the trunk and head but a sensory fit may spread to the extreme periphery first For example commencing in the fingers it may spread up the arm to the head or on reaching the shoulder it may invade trunk and leg before ascending to the head It may be bilateral and may be confined to the anterior or posterior aspect of the body

The sensation may be described as ' numbness , tingling pins and needles vibration , 'rushing' as if the limb were withering , much more rarely actual pain Sometimes the sensation is indescribable The sensory attacks have their origin in a local disturbance of the parietal region of the cortex and may indicate the presence of an organic lesion in that region They may be accompanied or followed by temporary loss of sensibility in the form of astereognosis, loss of sense of position or anæsthesia

Another group of sensory fits for which it is impossible to give any definite cerebral localisation at present is that of the so called visceral auras which are mainly referred to the distribution of the vagus nerve Such are the very commonly occurring epigastric sensation and sensations of choking dyspnœa nausea and cardiac sensations

Disturbances in the realm of the vestibular nerve are common indications of epilepsy Sudden giddiness may be the sole indication of epilepsy and is a common initial event in major attacks It may be indicative of the sudden fall of blood pressure or the feeling of rotation may be consequent upon early spasm causing conjugate deviation of the eyes

PSYCHO MOTOR FITS—These may take the form of peculiar mental states of instantaneous onset remembered afterwards sometimes in exquisite detail some times only in vague character Emotional conditions of fear or horror which may cause the patient to attempt with violence to escape from his surroundings— cur sive epilepsy—may occur Or the attacks may take the form of a sudden feeling of misery or an intense sense of personal wrongdoing a sense of intense familiarity in surroundings which are unfamiliar a sudden sense of strangeness as in a patient whose fit was suddenly seeming to be somewhere else a sense of euphoria or of intense mental energy a dreamy state often associated with smacking of the lips and champing or swallowing movements which often has a pleasurable emotional tone Again the psychic fit may take the form of a highly complex and detailed hallucination Other psycho motor attacks may express themselves as outbursts of uncontrollable rage and in rare instances the patients make attacks of great ferocity on unoffending individuals and have no recollection of these incidents afterwards

MINOR EPILEPSY (*petit mal*)—The disturbances to which this term is given show considerable variation in degree but share in common the fact that there is a sudden impairment or loss of consciousness

Simple loss of consciousness—In this the commonest of all minor phenomena there is a simple break in the continuity of consciousness The train of thought and action is suddenly arrested for a few seconds and there is a sudden stillness of posture and facial expression which attracts the attention of a witness The face may show sudden pallor a vacant expression and curious fixity of the eyes with large pupils The patient does not fall or move or drop anything that he is holding In a few seconds the attack is over leaving the patient unable to describe what has happened perhaps a little confused for some seconds sometimes emotional and even hysterical More often he continues what he was about as if nothing had happened Such attacks sometimes occur very frequently even hundreds in a day

Simple loss of consciousness with falling—The patient suddenly falls without warn ing in the extended position and almost always prone so that his head reaches the

ground first and his forehead receives the bruise He regains consciousness immediately and picks himself up as if nothing had happened In another form of this type the head or the head and trunk alone are affected the patient does not fall but simply drops the head forward

Simple loss of consciousness with slight spasm —This forms a gradation from the above types to the definitely convulsive seizures The spasm is seen as conjugate deviation of the eyes, and perhaps of the head also, or it takes the form of laryngeal and respiratory action giving rise to a groaning noise or it may involve any part of the musculature

CONDITION AFTER ATTACKS —The epileptic fit may leave no after effects whatever even though it be severe but this is unusual On the other hand even the slightest attacks may cause conspicuous sequels Sleep and headache are very common especially following convulsive attacks and they may be alternative effects in that if sleep occur there is no headache, but if it be prevented there is severe headache The post epileptic paralysis of Todd has already been described and also the aphasia which may follow right sided attacks The mental state is usually affected by the attack, and returns to the normal sometimes quickly sometimes slowly Commonly the patient is dull and dazed speaking at random, unreceptive, irritable and does not fully recognise his surroundings Many patients especially women weep During this state of impaired consciousness the patient may pass into a condition of mental automatism in which various acts are performed in a conscious manner but of which no recollection is afterwards retained One patient always prepared for bed after her minor attacks, and on one occasion proceeded to undress in the stalls of a theatre The acts performed during post epileptic automatism may have no relation to the life and mentality of the patient He may do spiteful and criminal acts to those he dislikes This fact has an important bearing as regards the criminal responsibility of the epileptic These post epileptic conditions occur commonly after minor attacks but they may also occur after major fits they seldom occur when convulsion has been severe

Vomiting may occur after any type of epileptic fit but it is most often met with after a convulsive attack As it occurs during the period of unconsciousness there is some danger of the vomited material being drawn into the larynx Though Gowers mentions a case in which this event proved fatal accidents of this nature are exceedingly rare

MENTAL DETERIORATION AND ABERRATION IN EPILEPSY —Many epileptics especially those who have frequent attacks show signs of mental deterioration which is often progressive and which may become severe and end in chronic insanity while others show no such mental troubles and some of these fulfil a long life with the highest standard of capacity

There seems to be no correlation between the type of epilepsy and mental degeneration though the latter is widely held to be more frequent and more severe when many minor attacks occur

The tendency to mental failure is greatest in the cases which commence in childhood and lessens as age increases but in the epilepsy commencing in the degenerative period of later life the incidence again increases In its slighter form there is merely defect of memory of attention and power of acquisition In more severe degree there is greater imperfection of intellectual power weakened capacity for attention and often defective moral control Mischievous restlessness and irritability may develop into vicious and criminal tendencies with advancing age Every grade of intellectual defect may be met with to actual imbecility Paroxysmal outbursts of mental derangement may occur sometimes transient and immediately following a fit sometimes without a fit and sometimes lasting for weeks or months

PERIODICITY —While some patients may have fits at any time and at all times yet there is a tendency in the majority for the attacks to occur at particular epochs

and not at others Epilepsy may be strictly ' nocturnal ' or diurnal ' It may occur only on rising in the morning or solely at the menstrual epoch The fits may come in batches of several in one day at intervals of many months A knowledge of the periodicity when present is of great value in the successful treatment of epilepsy

SPECIAL VARIETIES OF EPILEPSY

EPILEPSY FROM LOCAL DISEASE OF THE BRAIN —Almost any lesion of the cerebral hemispheres may produce symptomatic epilepsy But not more than 5 per cent of all such lesions do this The convulsions which may occur in cerebral thrombosis encephalitis and meningitis are examples of epilepsy incident with the onset of an acute lesion Lesions of the brain in childhood seem to be more commonly associated with epilepsy than when occurring in adult life Agenetic states of the brain of prenatal origin (cerebral diplegias) are associated with epilepsy in 30 per cent of the cases and infantile hemiplegia is followed by epilepsy in about the same proportion In adults the commonest causes of symptomatic epilepsy are supra tentorial tumours and cerebral syphilis Increased intracranial pressure by itself as for example in subtentorial tumours seldom if ever, produce fits unless there is associated involve ment of the hemispheres as occurs in meningitis subarachnoid hæmorrhage or hemi sphere tumours Cerebral abscess situated in the hemispheres not uncommonly produces fits

The fits caused by local lesions may be in every respect identical with and in distinguishable from the usual type of epileptic manifestation from the slightest momentary minor fit all through the local sensory and motor fits to the severe general convulsion of instantaneous onset and immediate loss of consciousness There are the same auras and the same sequels It may perhaps be said with relative truth that the splanchnic auras (epigastric cardiac etc) are uncommon and that there is a greater tendency for consciousness to be lost late

The minor attack is the least common fit occurring as the result of a local lesion the general convulsion by far the most common while the local fit holds an inter mediate position and its nature is often indicative of the position of the lesion

TRAUMATIC EPILEPSY —Special reference may be made to one of the examples of epilepsy caused by organic cerebral change namely trauma on account of the increasing incidence of head injury both in civilian life and as a result of war It is generally accepted that the underlying pathological change in traumatic epilepsy is the development of a cortical cicatrix although the occurrence or otherwise of epilepsy following such scar formation will be largely determined by the degree of stability of the particular brain affected

The incidence of traumatic epilepsy is variously estimated by different writers but it is agreed that the incidence is much higher in penetrating than in closed injuries of the brain In the case of closed injuries of all severity the estimates range from 4 per cent to 8 per cent the liability increasing with the severity of the injury as judged by the duration of unconsciousness In penetrating wounds of the brain estimates vary from 10 per cent to 25 per cent and Symonds suggests that 15 per cent represents the approximate incidence The development of epilepsy character istically follows a considerable latent interval which varies from a few months to many years and averages 2 to 3 years

In another group of cases however the fits seem to coincide with the process of healing the attacks beginning within a month or two of the injury and ceasing after 1½ or 2 years

Any form of epileptic disturbance may follow trauma but the generalised convul sion is the most common and it is not infrequently associated with typical attacks of *petit mal*

PYKNOLEPSY —This is a *form occurring in children, so called* because of the great number of the fits which may occur daily These are of the slight minor type any sign of spasm being infrequent It is rare for any major fit to occur There is no mental impairment whatever no deterioration of health and no result is obtained by any *form* of treatment The malady invariably ends in spontaneous cure usually before or at the age of puberty Its separation from minor epilepsy is of uncertain validity

CARDIAC EPILEPSY —This is a convenient term for the epilepsy which occurs in Adams Stokes' disease and in paroxysmal tachycardia and for the fits which may occur in congenital heart disease and in some forms of cyanosis They are probably related to sudden cerebral anoxia

VASO VAGAL ATTACKS —Under this misleading title Gowers described a recurrent paroxysmal symptom complex with some or all of the following components a sensation of fullness in the epigastrium, præcordial pain or discomfort, difficulty in breathing a sense of impending death a slowness of mental operations but without disturbance of consciousness, a sense of physical fatigue and coldness of face and extremities These symptoms wax and then wane gradually and may be present for as long as 4 hours from onset to disappearance

Gowers stated that he used the term " vaso vagal as a purely descriptive one but without *implying any theory of causation Unfortunately those who have adopted* his terminology have overlooked its lack of foundation The term has no precise meaning no sound basis of observation and no proper place in neurological terminology

MYOCLONUS EPILEPSY —In this group are included (1) Epilepsy *of an ordinary* type in which there is much epileptic jactitation of the muscles between the fits (2) cases of Unverricht s myoclonus in which epilepsy is coincident

REFLEX EPILEPSY —Numerous cases are on record in which fits could be produced with great regularity by certain specific stimuli To these the term reflex epilepsy has been applied The most frequent of such exciting causes is some tactile stimulus to a particular part of the body especially when unexpected In another form the stimulus may be a sudden noise or music Other cases are precipitated by emotion

EPILEPSIA PARTIALIS CONTINUA (*focal status epilepticus*) —Under this name have been described cases of focal epilepsy usually consisting of clonic spasm which remain confined to the part of the body in which they originate but which persist *with little or no intermission for hours or days at a stretch*

This form of epileptic discharge is most often seen in the face and is probably always associated with local organic disease of the corresponding area of the cerebral cortex

STATUS EPILEPTICUS —In this condition severe convulsion succeeds severe convulsion at short intervals without any return of consciousness during these intervals It is as if convulsion recurred as soon as the body recovered sufficiently from the exhaustion produced by the last convulsion Meanwhile the temperature rises and may reach a hyperpyrexia The difficulty in feeding and providing fluids the severe muscular exertion and the pyrexia add their dangers to those of exhaustion and the patient is very apt to succumb—usually to a terminal broncho pneumonia Status epilepticus must not be confused with frequently recurring fits in which there is some return to consciousness during the intervals though it frequently develops from such a condition for the latter is not accompanied by a rising temperature the fits are more readily subdued, and are not of nearly so severe a prognostic import If the convulsions of status epilepticus cannot be stopped by treatment the patient usually dies from sudden collapse or the first ceasing he remains delirious for a while with rapid heart and high temperature and dies of broncho pneumonia *Status* epilepticus may be met with in acute lesions of the brain and in chronic lesions such as general paralysis of the insane It may occur in acute poisoning with lead bismuth

and absinthe It may develop suddenly in any type of epilepsy whatsoever sometimes without apparent cause sometimes as the result of over exertion and excitement sometimes when medicines which have been regularly administered and which have kept the fits in check are suddenly cut off

Diagnosis—The recognition of epilepsy requires a working acquaintance with the nature of its many manifestations and especially of the slight forms little exterior ised which may be easily overlooked or misinterpreted The sudden unexpected onset without cause the transiency, the recurrence and the circumstances of the moment are useful aids If all these clinical features are taken into account a con fident diagnosis can almost invariably be made Epilepsy (idiopathic or symptomatic) is the only condition which causes attacks in sleep with the exception of the nightmare and the latter seldom causes difficulty in diagnosis Again if an attack occurs soon after waking there is a very strong presumption that it is epileptic The electroencephalogram is seldom helpful in the primary diagnosis but may give useful indications in the differentiation between idiopathic and symptomatic varieties The water-retention test, which seeks to provoke a fit for diagnostic purposes is rarely justifiable unless malingering is strongly suspected

Syncopal attacks (rapid lowering of blood pressure) can often be distinguished from epilepsy by their slow onset, the gradually increasing pallor or greyness the distancing of sound the nausea and flatulence the presence of an obvious cause their duration and the absence of any convulsive element

The hysterical attack has to be distinguished from the convulsion of epilepsy Hysterical convulsion has not the manner nor the march of epileptic spasm It never begins with conjugate deviation of head and eyes to one side there is not the orderly spread of convulsion and there is never anything but a poor imitation of the sequence of tonic followed by clonic spasms The movements in the hysterical fit are purposive spectacular violent and are liable to be increased by restraint and are rapidly abolished by complete inattention The hysterical fit never occurs except in the presence of an audience for it would then be purposeless and it never occurs during sleep the tongue is never bitten though other parts of the body and other people may be There is no transient abolition of the tendon jerks nor transient appearance of the Babinski plantar response The sphincters are never relaxed Intense converging spasm of the eyes is a common feature of the hysterical attack but this sign is not met with in epilepsy When elaborate disorders of behaviour follow slight and rapidly transient epileptic attacks the distinction between these and purely hysterical attacks is often difficult and sometimes impossible except after long observation for the initial epileptic attack may be practically unnoticeable and the subsequent events may be typical of hysteria and are usually amenable to the same line of treatment Often some point in the circumstances under which the attack occurs will settle the diagnosis Any attack having occurred during sleep or any attack in which the patient has fallen in circumstances of serious danger as among the traffic of a London street or any attack occurring when the patient cannot attract the attention of others establishes the diagnosis of epilepsy The best plan is to regard all fits as possibly epileptic and every fit of doubtful type as probably epileptic until time and circumstance bring definite conviction

Migraine may sometimes closely simulate epilepsy when sudden paralysis or sensory auras or visual hallucinations occur without headache But while the sensory phenomena of migraine may last for 5 to 30 minutes those of epilepsy have a duration of seconds only

Careful search must be made in every case for all the bodily conditions with which symptomatic epilepsy may be associated Papillœdema headache and vomiting may reveal increased intracranial pressure from some lesion of the brain while local paralysis sensory loss visual or other defect may indicate a local lesion of the brain past or present and this may also be suggested by the nature of a local fit. The

presence of rickets infantilism undue adiposity, etc may indicate the presence of some definite metabolic or endocrine disorder Renal function and the condition of the blood pressure should always be examined for even in early infancy fits may be uræmic and in the recurring convulsive attacks associated with chronic nephritis and with cystic renal disease and arterial hypertension the causal disease is frequently unrecognised Where syphilis is likely, the reactions in the blood and cerebrospinal fluid should be examined Lastly any evidence of chronic intoxication by metals, alcohol absinthe etc should be sought for

Cysticercosis epilepsy should be thought of when the patient has lived abroad Diagnosis depends upon the palpation of cysts in the tissues or the shadows in radio graphs of calcified cysts in the muscles, particularly those of the shoulders thighs and calves or within the skull

Prognosis —The outlook in epilepsy is so variable that it is difficult to indicate any but the broadest principles in prognosis Nor can a definite forecast be made in any case until the result of treatment has been watched for some time, for cases apparently favourable may prove rebellious and those apparently most unfavourable may turn out brilliant successes Speaking generally a cheerful outlook is justified in all cases except those in which there is progressive mental deterioration, and in these the outlook is hopeless in proportion to the rapidity of the mental change Naturally, in those cases which are associated with serious bodily disease such as brain tumour renal disease and hypertension the prognosis involves that of the exciting condition

The danger to life from the epileptic attack itself either directly or indirectly is not great However severe the fit it is extremely rare for death to occur and when this happens it is from turning over and smothering with the wetted pillow or by choking from the aspiration of vomited material Injury burning and drowning may cause death yet the number of epileptics who meet their deaths in this way is so infinitely small as almost to remove the danger of accident from practical per spective In the rare status epilepticus however the danger to life may be very great Spontaneous cessation of the attacks occurs in a proportion of cases The convulsive attacks of infancy, which continue for some years after all cause to which they can be attributed has passed away, often cease for ever at the age of 4 to 6 years Again after 20 years of age spontaneous cessation is met with

The probability of cure arrest or amelioration by treatment may be entertained in all cases where no mental deterioration exists and where no insuperable bodily disease determines the epilepsy in proportion as the only method of cure—the securing arrest of the attacks for a considerable time by drug treatment—can be adequately administered over a long period It is greater when periodicity in the occurrence of fits allows these to be anticipated by drug administration It is much greater when the following out of education or the continuance of regular employ ment allows of a fully occupied and satisfying life and much less when education is stopped pleasures and sports forbidden and the patient condemned to social inferiority and ostracism and to a gloomy narrow life of frustration because he has a few fits It is perhaps smallest when severe attacks occur daily or at short intervals and when both major and minor attacks occur in the same subject

Treatment —*General treatment* —The general principles for the maintenance of health if good or for its improvement if poor should be adopted Whenever possible no change whatever should be made from the régime of life of a normal person In childhood education discipline and pleasures and school life should be continued upon strictly normal lines and the adult should continue with work and occupation The life of the epileptic should be as regular as possible and physical and emotional strains changes in occupation and diet should be reduced to a minimum Continuity of treatment is of great importance and any course adopted should be given a thorough trial before being modified Frequent changes of doctor should be

avoided No advantage has accrued from the adoption of special diets such as the prohibition of meat the exclusion of salt or the use of purine free foods though the production of a low grade of acidosis by a ketogenic diet is occasionally of value in the epilepsy of children Alcohol seems to be an excitant of the epileptic attack and should be forbidden

The forbidding of such pastimes as may be fraught with danger should a fit occur, such as swimming boating, cycling and car driving, may be necessary

Marriage and pregnancy —The subject of epilepsy sometimes seeks—but rarely heeds—advice as to the expediency of marriage both in its effects upon himself (or herself) and in respect of any heritable qualities it may possess Marriage has no necessary effect upon the course of epilepsy and as we have seen direct trans mission of the disease is not usual Therefore the sweeping medical prohibitions once so frequent in these circumstances are not in fact warranted by such knowledge as we possess Every case must be considered on its merits It is common though not constant for fits to cease in the epileptic woman when pregnant and in any event the occurrence of fits at this time constitutes no special danger and is not an indication for the artificial termination of pregnancy On the other hand the con firmed and serious epileptic is clearly unlikely to be able to discharge adequately the responsibilities of parenthood

Institutional treatment —In cases where there is low mentality much mental degeneration or insanity and cases with frequent fits where no adequate care and occupation can be provided at home there is every advantage in a colony institution or asylum for epileptics In such patients regular work discipline and interest often mitigate greatly the burden of the malady

Surgical treatment —In the present state of our knowledge surgery has no part to play in the treatment of idiopathic epilepsy Neuro surgical procedures such as encephalography and ventriculography are of great value in establishing or excluding the presence of a space occupying lesion in doubtful cases and in revealing the presence of cortical atrophy porencephaly or ventricular dilatation Such epileptogenic pro-cesses as cerebral tumours or abscesses may be amenable to surgical removal and the epilepsy may be relieved thereby The value of surgery in traumatic epilepsy is more debatable Foerster and Penfield and others have demonstrated the value of the excision of scarred areas of the cortex in selected cases of traumatic epilepsy but demand as criteria for operation that ventriculography should reveal a definite ven-tricular distortion in that area of the brain indicated as the starting point of the dis charge by the nature of the fits and that it should be possible to reproduce an accurate replica of the fit by electrical stimulation of the abnormal area of cortex at the time of operation In many cases of traumatic epilepsy the cortical scarring plays only a precipitating role and there is in addition an inherent instability of the cortex In such cases excision of the scar affords only temporary relief and the fits soon recur in unaltered frequency

Medicinal treatment —Further than the measures above described the treatment of epilepsy is purely medicinal There are now several groups of drugs which have a remarkable effect in arresting or mitigating the occurrence of the attacks in epilepsy They seem to have much the same effect and may conveniently be combined or alternated in the treatment of any given case Sometimes one group is found to suit an individual patient better than the other Moderate doses such as will cause no deterioration in bodily or mental health even if taken regularly and for years seem to bring about the best results

The bromides formerly used universally have been almost completely displaced by the malonyl urea compounds of which phenobarbitone (Luminal) and soluble phenobarbitone are examples These are powerful drugs and must be u ed with care Phenobarbitone has certainly the advantage over soluble phenobarbitone in being more prolonged in its action It is conveniently prescribed in doses of gr $\frac{1}{8}$ to $\frac{1}{2}$

to a child and gr ¼ with a maximum dose of gr 1½ three times in the day to an adult. In larger doses it is a powerful hypnotic and in patients who have idiosyncrasy it may produce toxic symptoms In occasional cases it makes the patients peculiarly quarrelsome

A more recent introduction is primidone (Mysoline) which promises to be almost as useful an anti convulsant as phenobarbitone It is issued in tablets of 0 25 g of which from 1 to 6 may be taken in the day The toxicity of primidone is low and by itself it is not strongly hypnotic but if taken in association with phenobarbitone it may cause excessive drowsiness Another remedy is phenytoin sodium (Dilantin Epanutin Solantoin) which is usually dispensed in capsules of gr 1½ (0 1 g) For adults, 1 or 2 capsules may be given twice or thrice daily and smaller doses for children in proportion to size This drug has the merit of being less hypnotic than phenobarbitone but it is of less general usefulness and far more often produces toxic effects Of the latter, hypertrophy of the gums is the most characteristic but rashes and tremor also occur Phenytoin sodium has its most successful employ ment in cases in which nocturnal fits are numerous, two capsules being given (to an adult) at bedtime If it is decided to make a change to phenytoin sodium from some other medication this should be done gradually over several weeks

Recently the substance troxidone (Tridione) has been employed in the treatment of *petit mal* Given in doses of 0 3 g twice or thrice daily it has a striking effect in a minority of cases The occurrence of major attacks is a contraindication to its use and it is liable to give rise to toxic symptoms of which agranulocytosis is the most important It should therefore only be given under careful observation and when the treatment can be controlled by regular blood examinations

Many other remedies have been advocated in epilepsy a few only have stood the test of time and are still in use, both as alternatives and adjuvants to the treat ment above given These may be placed in order of merit as belladonna digitalis and borax

Whatever remedy is chosen it is essential if possible to anticipate the occurrence of the fit by the administration of the drug Thus if fits are nocturnal only the remedy is given in a single dose at night or if diurnal only, in a single dose in the early morning Again if as often happens the fits occur soon after waking then the single nightly dose should be used Or, if the fits occur or are more frequent at the menstrual epoch they should be anticipated by increased dosage before and during that epoch With fits that are diurnal and nocturnal a night and morning dose should be used Some patients do best on phenobarbitone alone others on another remedy alone and others on a combination of drugs and the best course can only be deter mined after trial

STATUS EPILEPTICUS —The treatment of this condition and that of rapidly re peated fits which not infrequently merges into status epilepticus is one of urgency and constitutes one of the important neurological emergencies

The first thing to be done is to check the convulsion and this is best achieved by inducing a state of light anæsthesia For this purpose paraldehyde in large doses is perhaps the safest and most effective drug If it can be administered by mouth ½ to 1 oz should be used in the case of an average adult or alternatively 1 to 2 oz may be given per rectum Subsequently smaller doses should be given every 2 to 3 hours in order to maintain a state of light narcosis the amounts being judged by the depth of unconsciousness and the occurrence of fits Alternatively amylobarbitone sodium (Sodium Amytal) gr 7½ given intravenously which is very effective may be employed If fits of great frequency and violence are present at the outset the situation can usually be temporarily controlled by the light administration of chloro form by inhalation Morphine gr $\frac{1}{6}$ with hyoscine gr $\frac{1}{100}$ may be of great value in controlling the restlessness of patients emerging from status but should be used with great caution owing to their depressant effect on the respiratory centre and

the danger of broncho pneumonia Together with the more immediately acting drugs phenobarbitone (gr 3) in the soluble form may be given intramuscularly and if necessary repeated in 12 hours Chloral and bromide are usually quite ineffective

An early opportunity should be taken to promote a vigorous action of the bowel either by the administration of a rapidly acting aperient such as castor oil by mouth or by an enema Care must be taken to protect the tongue from being bitten and to keep the mouth free from saliva and vomitus Tongue forceps should be at hand in case the tongue be swallowed during a period of coma and the patient should never be left alone As far as possible the chest should be supported on pillows between fits and the patient should be nursed on alternate sides Where persistent cyanosis is marked oxygen may be given together with 5 per cent carbon dioxide where hyperventilation is conspicuous Adequate fluid should be given preferably by mouth but when this is impossible by subcutaneous, intravenous or rectal drip of 5 per cent glucose in normal saline As consciousness returns a highly nutritious diet should be given in small frequent meals Hyperpyrexia may be controlled by frequent sponging or even by immersion in a tepid bath When consciousness returns the routine treatment of epilepsy should be resumed Status epilepticus carries a considerable mortality and death commonly occurs from broncho pneumonia or from cardiac failure Not infrequently status epilepticus is the terminal event in cases of chronic epilepsy

NARCOLEPSY

In this remarkable syndrome originally described by Gelineau and subsequently in greater detail by Adie and Wilson two quite different kinds of attack occur

The one is the onset of apparently normal sleep which comes on especially at time of inattention or when the desire to sleep might normally be expected to occur *as for example after meals in public vehicles or during the performance of tedious* duties The sleep is preceded by a sensation of extreme drowsiness often amounting to an irresistible desire to sleep The sleeper is easily roused and is then perfectly normal but if left undisturbed may remain asleep for many minutes or even an hour or two Attempts to ward off the attack by voluntary effort lead to an increase in intensity of the craving for sleep until it is satisfied

The other form of attack consists of a sudden onset of weakness and tonelessness in the voluntary muscles to which the term *cataplexy* is applied These cataplectic attacks are almost invariably precipitated by sudden emotion such as anger pleasure surprise or anticipation and most often of all by events provoking laughter In a severe attack when the emotion reaches a certain intensity the muscles suddenly become limp the head falls forward the jaw drops the eyelids close and the face becomes expressionless the arms fall to the sides and the legs crumple so that the patient sinks to the ground an inert mass speechless and incapable of the slightest movement but without any impairment of consciousness In a second or two the attack passes and the muscles immediately regain their normal condition Milder attacks may involve any part of the musculature or may consist merely of a momentary feeling of weakness of the knees Patients can often judge with great accuracy the intensity and nature of the emotion necessary to bring on an attack

Although most commonly the sleep attacks and cataplectic attacks occur under the characteristic circumstances in the same patients each may occur in isolation Often the patient complaining of one form of attack will admit to the other upon questioning though it may have been of rare occurrence and have caused little inconvenience

In the majority of patients suffering from narcolepsy examination reveals no evidence of organic disease in the nervous system or elsewhere and pathological

investigation is equally negative In such cases the term idiopathic narcolepsy can properly be applied Males are much more commonly affected than females, and though the attacks may begin at any age a large proportion have their onset between the ages of 10 and 30 and may continue throughout life In such cases it seems probable that we are dealing with a spasmodic disturbance of function of the nervous system comparable in many ways to epilepsy, though at present we have no clue to the cause of the disorder

In rare cases the narcoleptic syndrome may occur as a symptom of organic disease of the nervous system notably of encephalitis lethargica tumours of the third ventricle or hypothalamus and cerebral syphilis This association suggests that the site of the disturbance is in the autonomic centres of the hypothalamus and the floor of the third ventricle

Treatment —The sleep attacks of narcolepsy are in many cases greatly improved by the regular use of amphetamine sulphate An initial dose of 10 mg after break fast and lunch is often enough but this may be increased if necessary to 20 mg b d or even 30 mg b d Symptoms of overdosage are sleeplessness restlessness and tremulousness Less efficacious but of undoubted value in some cases is ephedrine sulphate in doses of gr ½ to 1 b d

Neither of these drugs is of comparable value in controlling the cataplectic attacks which usually remain resistant but can often be adequately prevented by the careful avoidance of the emotional stimulus which brings them on

MIGRAINE

Synonyms —Hemicrania Sick Headaches

Definition —A common malady of which the only essential characteristic is recurring intense headaches which usually develop on waking in the morning and which while often unilateral may be bi frontal occipital or general The attacks usually date from childhood but sometimes commence in later life The headaches are often associated with nausea and vomiting which has given rise to the designation sick headaches or bilious attacks and also with peculiar disturbances of vision and with giddiness suggestive of vestibular disturbance Less common symptoms of the disorder are varieties of slow sensory auræ which occur in no other malady attacks of hemiplegia or monoplegia or of aphasia and attacks of ophthalmoplegia Some of the phenomena may accompany the headaches but others occur in attacks quite apart from the headaches and may for that reason give rise to difficulty in diagnosis

Ætiology —The malady may originate in early childhood but commonly makes its appearance at about the age of puberty and tends to persist with fluctuations in the severity and frequency of attacks throughout adult and middle life It often ceases in women at the menopause and its persistence into old age in either sex is exceptional The sexes are equally affected and a history of family incidence is com mon In other cases a family history of such paroxysmal disorders as hay fever asthma urticaria or epilepsy or of psychopathic tendencies may be obtained Subjects of migraine are commonly of an energetic and intelligent type and many have a meticulous standard of thoroughness and precision almost amounting to an obsession

Nothing is known with certainty as to the essential cause of migraine Numerous factors such as errors of refraction disorders of digestion and of endocrine function and psychological disturbances have all been evoked as responsible causes but it is probable that at most they are never more than precipitating factors in susceptible individuals There is considerable indirect evidence that the immediate cause of the attack is a paroxysmal variation in the calibre of the cerebral blood vessels either

spasm or dilatation or the one followed by the other but proof is at present lacking

Precipitating factors are numerous and may be very specific. On the psychological level fatigue anxiety and frustration play an important part On the physical plane over exertion and fatigue indiscretions or irregularities of food exposure to excessive light or noise prolonged eye strain especially in the presence of an uncorrected error of refraction commonly figure in the history of migrainous subjects Women usually have attacks in association with the menstrual periods and often remain entirely free during pregnancy

Symptoms —The subjects of migraine are usually otherwise quite healthy and are often robust and strong Premonitory signs of the attacks are present in some cases and these may take the form of an unusual feeling of well being and intellectual acuity or on the other hand of lassitude and depression

The attack commences most commonly on waking in the morning when on raising his head from the pillow the patient experiences a sense of giddiness ocular confusion and nausea such as is commonly felt at the onset of sea sickness It is at this stage of the attack and within a few minutes of its commencement that the visual phenomena occur if these are present Often the patient vomits at once but some times vomiting is delayed for hours but may continue throughout the attack with great prostration sweating and coldness of the extremities The visual disturbances last but a short time (from 10 to 30 minutes) but leave as a rule some confusion of vision and discomfort throughout the attack The headache follows shortly after these initial symptoms It is cumulative and throbbing in character and often begins constantly in a localised spot over one eye or in the temple as a sharp boring pain which gradually spreads and may involve the neck and arm The pain may be unilateral frontal occipital or quite general but is usually constant from attack to attack As the headache increases in severity the face becomes pale and grey, the patient becomes much prostrated and is incapable of mental or physical effort and unable to take food Light noise and movement aggravate the pain intolerably and the patient seeks the refuge of his bed in a darkened room After remaining in this condition for some hours he falls into a deep sleep and wakes next day shaken by his illness but otherwise well

The above description covers many attacks of migraine but many variations occur The attacks do not always occur on waking they may come on at any time of the day or at night They may be rapidly transient lasting for a few hours only or they may last for days and give rise to much anxiety in the attempt to provide nourishment and sleep for the patient It is not uncommon for them to change their character gradually as the patient gets older and in cases of long standing the patient may complain of a persistent annoying headache between the attacks In other cases the headache may be relatively inconspicuous compared with the vomiting and the various sensory disturbance

Visual phenomena —Considering how very common migraine is it must be clearly understood that any visual phenomena except slight confusion of vision accompanying the attacks are rare They may take the form of general mistiness of vision floating spots scotomata bright stars and colours hemianopia double hemianopia with com plete blindness or psychic hallucinations of vision In connection with scotoma and with hemianopia the phenomenon of teichopsia may occur as follows Upon the dark background of the scotoma or hemianopic field a ball of light appears which grows larger and becomes dark in the centre This ring of light breaks at one spot opens out and takes the form of a series of entering and retreating angles (castellation figure) which become gloriously coloured (fortification spectrum) and which later become fragmented and fade These visual events usually occur at the very beginning of the attack before the headache develops and they are rapidly evanescent but they may occur as isolated phenomena when no headache occurs

Aphasic attacks may take the form of confusion of speech word blindness or even

loss of speech acceptance and exteriorisation They accompany the headaches and occur at the commencement of the attacks They are not of common occurrence

Sensory auræ —These are somewhat rare events but *they are pathognomonic of* migraine and may occur quite apart from the headaches The aura commences upon the periphery of a limb and is likened to that which would be produced by a multitude of cold footed insects creeping on the skin It travels very slowly proximally taking half an hour or more to reach from the fingers to the head and is very alarming to the patient It disappears rapidly without further event It is the only aura with an exceedingly slow spread Another form of sensory aura occasionally encountered is numbness of the lips and tongue

Ophthalmoplegia —This is a very rare but most important event It occurs only at the height of the headache, in severe attacks Indeed the patients usually say that the headache, during which the ophthalmoplegia occurred, was the very worst they had ever experienced It is a partial paralysis of the oculo motor nerve trunks most commonly of the sixth nerve alone but sometimes of the third or fourth nerves or of a combination of these three It is generally unilateral, but may occur simultaneously on both sides Severe diplopia results It passes off in from a few days to a few weeks When once it has occurred it is apt to recur with subsequent attacks Attacks of this kind have been called ophthalmoplegic migraine but it should be *realised that the ophthalmoplegia and the migraine syndrome are symptomatic of* some organic intracranial disease the nature of this cannot always be discovered by the means at present at our disposal but in many instances it is an aneurysm or angiomatous malformation which may be revealed by arteriography

Diagnosis —*In typical cases the diagnosis of migraine is seldom in doubt* The long history the familial incidence and the common association of headache with vomiting and various sensory disturbances all contribute to a characteristic clinical picture When however these varied manifestations occur alone considerable difficulty may be experienced

It is important to remember that tumours of the occipital lobes and intracranial aneurysms may be associated with attacks exactly resembling migraine and every case should be carefully examined for signs of organic nervous disease particularly papillœdema or persistent defects in the fields of vision It is probable that the so called ophthalmoplegic migraine in many cases at least is a symptom complex distinct from true migraine and dependent upon a gross intracranial lesion most often an aneurysm on one of the component vessels of the circle of Willis Hypertension with or without chronic renal disease, may be associated with headaches closely resembling migraine and an examination *of the blood pressure and of the* urine should never be omitted Headaches of neurotic origin may closely simulate migraine particularly when as is not infrequently the case they are superimposed upon a background of true migraine It is exceedingly rare for migraine to recur *more often than once in 2 or 3 weeks* or to last more than 2 days in persons without a strong neurotic tendency

Those who are not familiar with the full range of sensory symptoms that may precede the onset of the headache and do not realise the severity of the speech disturbances which in some cases accompany them are apt to take an unduly grave and erroneous view of the history given by a patient who has experienced them Thus a diagnosis of epilepsy or of cerebral tumour is not infrequently made It should therefore be remembered that the disturbances of sensation which occur in epileptic attacks are momentary in duration and never persist as do the migrainous symptoms in question for many minutes *Again consciousness is neither* blunted nor lost in migraine

Attacks of migraine consisting wholly of vomiting and sometimes associated with diarrhœa and abdominal discomfort are readily mistaken for abdominal disorders

Treatment —Few non fatal disorders are more stubbornly resistant to treatment

than migraine Many victims suffer from recurring attacks throughout the most valuable years of their lives to the serious detriment of their work and happiness In many cases help can be given by attention to general health and physical and mental well being for a lowering of these in a migrainous subject seldom fails to evoke an increase in the number and severity of attacks In others it may be possible to eliminate precipitating factors whether physical or psychological in nature but only too often when these are discoverable they are found to be amongst the unalterable features of the patient s environment

Drugs administered consistently over a long period may be of value in some cases and of these phenobarbitone gr ½ twice daily or gr 1 at night is perhaps the most generally useful Gowers mixture containing min 1 of liq trinitrini min 5 of liq strychninæ min 10 of tinct gelsemii and gr 10 of sodium bromide administered thrice daily has long enjoyed a favourable reputation largely from lack of competition The individual attacks are equally difficult to relieve Sometimes a full dose of phenazone acetanilide phenacetin or aspirin given at the very commencement of an attack will ward it off but are useless when once the headache is fully developed Ergotamine tartrate (Femergin) in doses of ½ to 1 mg by mouth or injection will sometimes cut short an attack but is by no means the specific that has been claimed When attacks are frequent one or two tablets of ergotamine tartrate daily may be used as a prophylactic Apart from these remedies it remains to keep the patient as comfortable as possible and to induce sleep by the use of ordinary hypnotics and to secure that the patient takes adequate fluids and nourishment during a prolonged attack

DISORDERS CHARACTERISED BY INVOLUNTARY MOVEMENTS

WILSON S DISEASE *(see p 1484)*

PARALYSIS AGITANS

Synonyms —Parkinson s Disease The Shaking Palsy

Definition —A progressive disease of insidious onset and slow course usually occurring in the second half of life and characterised by loss of the normal associated movements and by a peculiar stiffness of the muscles which give rise to a distinctive facial expression bodily attitude and gait The stiffness is accompanied by weakness and often by rhythmic tremors which have earned for this malady the name shaking palsy

Ætiology —Little is known of the causal factors of this malady It is essentially a disease of the decline of life and though in rare instances it is met with as early as the eighteenth year *the maximum incidence is from the fiftieth to the seventieth* year Men suffer twice as frequently as women Heredity seems to play no part in the causation

Pathology —No naked eye changes are to be found other than associated vascular and degenerative changes which are common in senile conditions The most definite pathological findings are degenerative changes in the cells and fibres of the corpus striatum and its efferent systems These changes are most marked in the globus pallidus of the lenticular nucleus but occur also in the putamen the caudate nucleus the corpus Luysii and the substantia nigra There is a constant loss of cells preceded by degenerative changes in those that remain An associated glial proliferation takes place in the affected regions together with fibrosis in the smallest arterioles and capillaries The relationship of these changes to the symptomatology of the disorder

loss of speech acceptance and exteriorisation They accompany the headaches and occur at the commencement of the attacks They are not of common occurrence

Sensory auræ —These are somewhat rare events, but they are pathognomonic of migraine and may occur quite apart from the headaches The aura commences upon the periphery of a limb and is likened to that which would be produced by a multitude of cold footed insects creeping on the skin It travels very slowly proximally, taking half an hour or more to reach from the fingers to the head and is very alarming to the patient It disappears rapidly without further event It is the only aura with an exceedingly slow spread Another form of sensory aura occasionally encountered is numbness of the lips and tongue

Ophthalmoplegia —This is a very rare but most important event It occurs only at the height of the headache in severe attacks Indeed the patients usually say that the headache, during which the ophthalmoplegia occurred was the very worst they had ever experienced It is a partial paralysis of the oculo motor nerve trunks most commonly of the sixth nerve alone but sometimes of the third or fourth nerves or of a combination of these three It is generally unilateral but may occur simultaneously on both sides Severe diplopia results It passes off in from a few days to a few weeks When once it has occurred it is apt to recur with subsequent attacks Attacks of this kind have been called ophthalmoplegic migraine, but it should be realised that the ophthalmoplegia and the migraine syndrome are symptomatic of some organic intracranial disease the nature of this cannot always be discovered by the means at present at our disposal but in many instances it is an aneurysm or angiomatous malformation which may be revealed by arteriography

Diagnosis —In typical cases the diagnosis of migraine is seldom in doubt The long history the familial incidence and the common association of headache with vomiting and various sensory disturbances all contribute to a characteristic clinical picture When however these varied manifestations occur alone considerable difficulty may be experienced

It is important to remember that tumours of the occipital lobes and intracranial aneurysms may be associated with attacks exactly resembling migraine and every case should be carefully examined for signs of organic nervous disease particularly papillœdema or persistent defects in the fields of vision It is probable that the so called ophthalmoplegic migraine in many cases at least is a symptom complex distinct from true migraine and dependent upon a gross intracranial lesion most often an aneurysm on one of the component vessels of the circle of Willis Hyper tension with or without chronic renal disease may be associated with headaches closely resembling migraine and an examination of the blood pressure and of the urine should never be omitted Headaches of neurotic origin may closely simulate migraine particularly when as is not infrequently the case they are superimposed upon a background of true migraine It is exceedingly rare for migraine to recur more often than once in 2 or 3 weeks or to last more than 2 days in persons without a strong neurotic tendency

Those who are not familiar with the full range of sensory symptoms that may precede the onset of the headache and do not realise the severity of the speech disturbances which in some cases accompany them are apt to take an unduly grave and erroneous view of the history given by a patient who has experienced them Thus a diagnosis of epilepsy or of cerebral tumour is not infrequently made It should therefore be remembered that the disturbances of sensation which occur in epileptic attacks are momentary in duration and never persist as do the migrainous symptoms in question for many minutes Again consciousness is neither blunted nor lost in migraine

Attacks of migraine consisting wholly of vomiting and sometimes associated with diarrhœa and abdominal discomfort are readily mistaken for abdominal disorders

Treatment —Few non fatal disorders are more stubbornly resistant to treatment

acteristic feature of the tremor in about one half of the cases is that it continues during repose and is temporarily arrested by the execution of volitional movement In the other half of the cases however the tremor appears or is increased on voluntary exertion and tends to be less during repose There seems to be an antagonism between the tremor and the rigidity for in cases where the rigidity is very conspicuous the tremor is little marked or absent and conversely when tremor is universal or is of early onset rigidity is a less noticeable feature

Other symptoms of the disease which are very commonly complained of are—(1) difficulty in turning over in bed which is the obvious result of the rigidity of the trunk muscles (2) flexion of the toes into the sole of the foot so that they are trodden on from spasm of the plantar muscles (3) pain of a dull aching character in the trunk and limbs which is presumably produced by the long continued traction of the rigid muscles upon their attachments (4) abnormal sensations of heat and cold and (5) hypersensitiveness to changes of temperature—the patient cannot bear to be near a fire nor yet in a cold room Mental symptoms are conspicuous by their absence except in the last stages of the malady when profound asthenia overtakes both mind and body The constant bodily discomfort, restlessness sensations of fatigue which the rigidity and the tremors engender and the consciousness of a malady which is found only too soon to resist every effort to lessen or arrest it often result in gloomy and lasting mental depression Objective sensibility is unimpaired The special senses and the cranial nerves are not affected The sphincters and the reflexes are normal Trophic changes in the periphery of the limbs thinning and glossiness of the skin with fluted nails and vasomotor disturbance are common Bed sore is commonly met with in the late stages of the malady

Diagnosis —There are three points which can be surely relied upon to render the diagnosis of paralysis agitans certain in every case namely—(1) the aspect of the patient when he is walking when the fixed mournful expression the stooping attitude with round shoulders the elbows pressed into the side and the hands carried across the abdomen in the interosseal position the immobility of the head and neck and the curious gliding gait which cannot fail immediately to arrest the observer s attention (2) the rhythmic rolling tremor which is quite unlike any other form of tremor and which often continues during rest and (3) the absence of any of the signs of disease of the pyramidal system Difficulty may perhaps be experienced when the aspect is little marked and the tremor is confined to some unusual situation such as the face tongue or neck but if the possibility of tremor in any situation being that of paralysis agitans be borne in mind its rhythmic rolling nature will give the diagnosis When paralysis agitans is confined to one side of the body the appearance of the patient may superficially resemble that of hemiplegia but in these cases the peculiar aspect of paralysis agitans is marked and the organic signs of hemiplegia such as the extensor response in the plantar reflex the increase in the deep reflexes and the absence of the abdominal reflex upon the paretic side are not present In senile tremor the rhythmic rolling quality is absent and the aspect is not that of paralysis agitans In post hemiplegic tremor the organic signs of hemiplegia are present Toxic tremor is irregular and never rhythmical and is (mercurial tremor excepted) a fine tremor The intention tremor of disseminated sclerosis cerebellar disease and lesions of the red nucleus are so peculiar and so widely different from the tremor of paralysis agitans as to render confusion impossible

The one clinical condition which may resemble paralysis agitans so closely as to be indistinguishable is the form of Parkinsonism which may appear as a sequela of encephalitis lethargica In this condition there are similarly placed changes in the basal ganglia brought about by the encephalitic virus Such post encephalitic cases commonly originate much earlier in life than paralysis agitans and there may be a history of the initial disease The onset is often more rapid and the condition may become arrested whereas paralysis agitans is invariably relentlessly progressive

is by no means clear the more so in view of the fact that in the post encephalitic cases the principal changes are found in the substantia nigra

Symptoms—The onset is always insidious and the paucity of movement and the muscular rigidity are almost always the first signs to appear This *rigidity* affects the face neck and trunk to a greater extent than the limbs and when the limbs are affected then the proximal muscles present a greater degree of rigidity than do those of the periphery The oncoming rigidity of the facial muscles does away with the usual play of the emotional movements in facial expression and the face assumes a fixed anxious and mask like expression, with absence of the usual involuntary nictitation The voice loses its inflexions and becomes monotonous from rigidity of the muscles of larynx tongue and lips, but there is no other defect of articulation Very striking is the effect of the rigidity of the muscles of the neck for the patient carries his head and neck in one piece with his trunk as if he were a statue, never inclining or raising it in the customary expressive manner and if he turns round to look at anything he tends to move the whole trunk round with the head In looking sharply to one side the eyes move before the head whereas under normal circumstances the coarse adjustment of this movement is done first by the neck muscles and the fine adjustment subsequently by the eye muscles The stiffness of the trunk muscles gives a stooping attitude with the head inclined forwards while that of the upper extremities causes the shoulders to be rounded and the arms carried with the elbow semiflexed and pressed into the sides The gait is highly characteristic in marked cases since on account of rigidity of muscles it is deprived of spring and suppleness the patient in the characteristic attitude above described takes small gliding steps displacing his centre of gravity as little as possible If by any circumstance such as catching the feet against an unevenness of the ground or a push the centre of gravity is much displaced the patient often has a difficulty in regaining it and in moving to recover his centre of gravity is unable quite to catch it up and so continues the movement of necessity until he fall or come in contact with some object by which he can arrest himself and restore his balance This phenomenon is more often seen in advanced cases and is known as propulsion retropulsion and lateripulsion according as the centre of gravity is displaced and the movement occurs in a forward backward or sideways direction Festination is the term used for the quickening of the pace sometimes seen in this attempt to overtake the displaced centre of gravity In the hand the rigidity is greater in the interosseal muscles and the hand therefore tends to assume the interosseal position with the fingers pressed together and the *thumb adducted the metacarpophalangeal joints being flexed and the interphalangeal* joints extended From this rigidity of the hand the writing becomes small as well as tremulous and the patient finds it difficult to write in a straight line Muscular weakness always accompanies the rigidity and the tremors It is slight until the late stages of the disease when it may increase rapidly and render all useful movement impossible On account of the rigidity and consequent slowness of movement the patient experiences a sense of weakness which is much greater than the actual weakness shown by the dynamometer *Tremor* is present in the majority of cases It usually commences in the hand and forearm and is most conspicuous in this situation but it may be seen in the face tongue jaw neck and feet while in rare cases it may be universal The nature of the tremor is peculiar and is highly characteristic It is a regular rhythmical contraction of the muscles alternating in the opposing groups with a frequency of from four to six oscillations per second with a range of from an eighth to three quarters of an inch Its rhythmic nature its slowness and its range distinguish it from other varieties of tremor In the hand the characteristic movement of the tremor is the rolling together of the opposed thumb and fingers cigarette rolling bread crumbling or drum tapping movement. There is nearly always in addition a peculiar pronator supinator tremor The tremor is increased by excitement and by self consciousness and ceases during sleep A highly char

acteristic feature of the tremor in about one half of the cases is that it continues during repose, and is temporarily arrested by the execution of volitional movement In the other half of the cases however the tremor appears or is increased on voluntary exertion and tends to be less during repose There seems to be an antagonism between the tremor and the rigidity for in cases where the rigidity is very conspicuous the tremor is little marked or absent and conversely, when tremor is universal or is of early onset rigidity is a less noticeable feature

Other symptoms of the disease which are very commonly complained of are—(1) difficulty in turning over in bed which is the obvious result of the rigidity of the trunk muscles (2) flexion of the toes into the sole of the foot so that they are trodden on from spasm of the plantar muscles (3) pain of a dull aching character in the trunk and limbs which is presumably produced by the long continued traction of the rigid muscles upon their attachments (4) abnormal sensations of heat and cold and (5) hypersensitiveness to changes of temperature—the patient cannot bear to be near a fire nor yet in a cold room Mental symptoms are conspicuous by their absence except in the last stages of the malady when profound asthenia overtakes both mind and body The constant bodily discomfort restlessness sensations of fatigue which the rigidity and the tremors engender and the consciousness of a malady which is found only too soon to resist every effort to lessen or arrest it often result in gloomy and lasting mental depression Objective sensibility is unimpaired The special senses and the cranial nerves are not affected The sphincters and the reflexes are normal Trophic changes in the periphery of the limbs thinning and glossiness of the skin with fluted nails and vasomotor disturbance are common Bed sore is commonly met with in the late stages of the malady

Diagnosis —There are three points which can be surely relied upon to render the diagnosis of paralysis agitans certain in every case namely—(1) the aspect of the patient when he is walking when the fixed mournful expression the stooping attitude with round shoulders the elbows pressed into the side and the hands carried across the abdomen in the interosseal position the immobility of the head and neck and the curious gliding gait which cannot fail immediately to arrest the observer s attention (2) the rhythmic rolling tremor which is quite unlike any other form of tremor and which often continues during rest and (3) the absence of any of the signs of disease of the pyramidal system Difficulty may perhaps be experienced when the aspect is little marked and the tremor is confined to some unusual situation such as the face tongue or neck but if the possibility of tremor in any situation being that of paralysis agitans be borne in mind its rhythmic rolling nature will give the diagnosis When paralysis agitans is confined to one side of the body the appearance of the patient may superficially resemble that of hemiplegia but in these cases the peculiar aspect of paralysis agitans is marked and the organic signs of hemiplegia such as the extensor response in the plantar reflex the increase in the deep reflexes and the absence of the abdominal reflex upon the paretic side are not present In senile tremor the rhythmic rolling quality is absent and the aspect is not that of paralysis agitans In post hemiplegic tremor the organic signs of hemiplegia are present Toxic tremor is irregular and never rhythmical and is (mercurial tremor excepted) a fine tremor The intention tremor of disseminated sclerosis cerebellar disease and lesions of the red nucleus are so peculiar and so widely different from the tremor of paralysis agitans as to render confusion impossible

The one clinical condition which may resemble paralysis agitans so closely as to be indistinguishable is the form of Parkinsonism which may appear as a sequela of encephalitis lethargica In this condition there are similarly placed changes in the basal ganglia brought about by the encephalitic virus Such post encephalitic cases commonly originate much earlier in life than paralysis agitans and there may be a history of the initial disease The onset is often more rapid and the condition may become arrested whereas paralysis agitans is invariably relentlessly progressive

Post encephalitic cases often manifest other sequelæ of the disease, notably oculogyric crises post encephalitic tics alteration in the pupils or external ocular muscles and changes in temperament These are absent in paralysis agitans

Course and Prognosis—Paralysis agitans often begins in one limb usually the upper, and spreads thence to the corresponding limb of the opposite or to the other limb of the same side In the latter case it has approximately a hemiplegic distribution and it may remain for years much more evident upon one side of the body The course is *slowly progressive with variable rate* In some cases the malady may remain stationary for years, and this is more often seen in middle aged subjects, before the disease has reached an incapacitating stage Such arrest in the early stages is not often seen in young subjects for in the latter the disease seems to take a more continuously downhill course Real improvement in the symptoms is never seen A fatal issue may occur in as short a time as 2 years, but this is exceptional, since paralysis agitans has little tendency to shorten life The average duration is from 10 to 15 years and *since the major incidence of the disease is in the sixth decade of life it will be seen* that many of the patients are of average longevity Death may occur from intercurrent maladies especially from bronchitis but more commonly after the lapse of many years the patient becomes bedridden from increasing weakness and rigidity and sinks into a condition of sleepy asthenia which is soon terminated by coma An unduly high blood pressure is unusual in the subjects of paralysis agitans and it is noteworthy that they do not suffer from gross cerebral vascular lesions such as thrombosis or hæmorrhage

Treatment—All that can be done to arrest or slow down the degenerative process which is responsible for the symptoms is general tonic treatment and the administration of those vitamin B elements which aid the general nourishment of the nervous system Palliative treatment is almost entirely medicinal Where there is much rigidity gentle exercise, passive movements and massage are useful *but electrical* treatment can do no good In using the various medicinal remedies which are available, it must be remembered first that all of them produce their effect for a few hours only and secondly that the patient s symptoms cease in any case during sleep It is therefore important that the patient should take the drugs at such times of the day as to obtain the maximum relief during those periods when he most desires it *and* it is useless to take them at night The most generally useful remedy is benzhexol hydrochloride (Artane) *which relieves* both the tremor and the rigidity though in occasional cases by reducing the rigidity it allows the tremor to increase It is issued in tablets each containing 2 mg or 5 mg and small doses should be given *until* the patient s tolerance of the drug is assured it can then be increased *gradually up* to 20 or 30 mg in the day until the maximum effect is obtained The symptoms of *intolerance are nausea and occasionally some blurring of vision*

The action of procyclidine hydrochloride (Kemadrin) is similar Drugs of the belladonna group have long been used—belladonna hyoscine stramonium atropine and of these hyoscine is in general the most valuable It may be given in tablets (each gr $\frac{1}{200}$) or in solution and the latter has the advantage that the dose is more easily varied (gr $\frac{1}{200}$ or $\frac{1}{100}$ *by mouth thrice daily in chloroform water*) If quickly absorbed it may produce feelings of confusion or faintness and should therefore not be taken when the stomach is empty but only after food The combination Rabellon contains hyoscine stramonium and atropine in tablet form

The progress of the disease is slow and the patient should be encouraged to maintain his *activities as long as possible nothing* is to be gained by rest When the patient is bedridden great care must be taken with the skin

Pains may be troublesome and can only be relieved with aspirin and similar analgesics The immobility of the limbs may cause arthritis in the *shoulders and* this should be guarded against by passive movements and when it occurs treated by the usual appropriate *measures*

CHOREA

Synonyms —St Vitus Dance Sydenham s Chorea Rheumatic Chorea

Definition —Chorea is an affection of the nervous system characterised by the occurrence of spontaneous involuntary movements, irregular both in time in extent and in place of occurrence and also by muscular weakness and by a variable degree of psychic disturbance

Ætiology —The important causal factor of the ordinary variety of chorea is acute or subacute rheumatism Chorea is much more common among the poorer classes than among the well to do Its incidence is upon nervous highly strung subjects rather than upon the phlegmatic and this is probably to be explained by the fact that the rheumatic subject is likely to be nervous and highly strung Chorea is practically unknown during the first 3 years of life and is very rare before the fifth year has passed Common between the ages of 5 to 10 years it reaches its maximum incidence between 10 and 15 years After the age of 20 it is rare except in pregnancy but a few cases have been reported up to the age of 60 years which have certainly been examples of rheumatic chorea Females are affected twice as frequently as are males Heredity concerns the incidence of chorea in two ways firstly in the inheritance of the rheumatic tendency which is the important cause of chorea and secondly in the inheritance of the neuropathic tendency for it is when these two are coincident that chorea is most prone to occur As early as 1802 rheumatism was regarded as the cause of chorea and all subsequent investigations have upheld this theory The family history of a choreic patient generally brings to light the occurrence of acute rheumatism of cardiac disease and of other rheumatic manifestations among other members of the family Often the patient has suffered with acute or subacute rheumatism growing pains rheumatic erythema purpura rheumatic nodules or recurrent sore throat before the appearance of the chorea and may be found to be already the subject of rheumatic heart disease A large percentage of those patients who have never shown any sign of the rheumatic state before or during the attack of chorea subsequently suffer with rheumatic symptoms The British Medical Association Collective Investigation Committee found that rheumatism preceded the chorea in 26 per cent of the cases and that in 46 per cent of the remainder rheumatic signs accompanied the chorea or appeared subsequently If to the total of choreic patients who present rheumatic signs at some time or other one adds those with no personal history of rheumatism but with a family history of rheumatism it will be found that there are but few cases of chorea in which a personal or family history of rheumatism is absent

Psychical disturbances —Any emotional disturbance such as fright anxiety depression or overpressure in school may sometimes act as an immediate determining factor but much more often these events simply aggravate symptoms which are already present in slight degree

Pregnancy —The relationship of pregnancy to chorea is very definite It is generally met with in first pregnancies and before the age of 25 years and in most cases the pregnancy appears to be the only immediate cause for the chorea but a history of rheumatic infection will often be obtained in a careful history The onset of the chorea is usually between the first and third months of pregnancy It is liable to recur with subsequent pregnancies

Pathology —The essential lesion has proved very difficult of detection by microscopical investigation but according to Greenfield and Wolfsohn it consists in a diffuse meningo encephalitis affecting mainly the basal ganglia the cerebral cortex and the pia arachnoid

Symptoms —The onset is usually gradual but it is sometimes abrupt when emotional disturbance has been the determining cause The appearance of choreic

movements is often preceded by alterations in the mental and physical condition of the child She becomes nervous and more impressionable than before She is increasingly unable to apply her attention She becomes clumsy in her movements—and lets fall objects which she is holding Anæmia apathy and languor and irregularity of appetite are commonly present At this time, careful observation will discover slight involuntary movements of the face and fingers which are often unilateral in distribution From day to day the movements become more marked and spread *to the limbs and trunk* *The face is constantly grimacing* and the hands and arms scarcely cease from turning about and affection of the legs makes the walking irregular and clumsy The child can no longer keep still the respiratory movements become irregular and spasmodic and the chorea is fully developed The characteristic symptoms of a well marked case of chorea are—(1) involuntary movements (2) *weakness of voluntary movements* (3) *ataxy or loss of precision of voluntary movement*, (4) emotional instability and other psychic disturbances

1 THE INVOLUNTARY MOVEMENTS are always irregular in time and in the form of the movement Similar movements are never repeated successively in the same part. Each movement begins rapidly and ends suddenly, and one frequently sees the involuntary movement complicated by the addition of a voluntary movement to cover the fault The majority of the movements are complicated involving several muscles and often more than one joint In the face the more simple movements take the form of asymmetrical twitches in the lips and about the angles of the mouth and orbits In more severe cases the strangest grimaces may occur The tongue is thrust into one cheek then put out and withdrawn just in time to escape the sudden snap of the open mouth When asked to show the tongue the child puts it out rapidly and holds it there by closing the teeth upon it Smacking of the tongue and palate may often be heard at a distance Lateral movement of the jaw is common According to the severity of the case speech may be difficult the words being articulated slowly in slurred monosyllables For the same reason swallowing may be difficult or impossible in severe cases and may necessitate nasal feeding The ocular muscles participate in the involuntary movements only in very severe cases

In the upper extremities the movements appear first in the hand The thumb is more restless than the fingers which are spread and pressed together flexed and extended alternately the wrists twist about irregularly the forearms are constantly agitated with movements of *pronation and supination flexion and extension* while all possible movements of the shoulder occur When the upper extremities are outstretched the hands assume the position of flexion at the wrist and over extension at all the finger joints in so many of the cases as to make this a characteristic feature of chorea The lower extremities are less severely affected than is the rest of the body and here the movements are best seen when the child is lying down The gait tends to be clumsy and insecure and in severe cases walking becomes impossible Alteration of the rhythm of the respiratory movements is conspicuous and is highly characteristic of chorea The breath is often taken rapidly and held for some time then let go with a loud sigh The trunk is often involved and movements of a writhing nature are characteristic

So far as the limbs are concerned the movements may be confined to *one side* more commonly the left side and the condition is then called hemichorea but the involvement of the face and trunk is always bilateral and is generally equal upon the two sides In hemichorea the movements are always of slight severity Severe chorea is never confined to one side Choreic movements cease during sleep and except *in severe cases* *can be controlled more* or less by voluntary effort the attempt to write for example will generally cause cessation of the movements of the right arm for the time being They are generally increased by observation emotion and self consciousness but in a few cases it will be found they are worse when the child is alone and unobserved The violence of the movements *of the limbs* may cause the

skin over the prominences to ulcerate from friction against their clothing and the head and limbs may be badly bruised from contact with adjacent objects and unless the patient be properly protected wounds may occur, which are liable to infection

2 LOSS OF POWER is shown in the mild cases by incapacity for exertion and undue fatigue More severe degrees of paresis may accompany or succeed the appearance of the movements It may be observed that in one limb, or upon one side of the body the choreic movements are becoming less marked, and that the limbs are becoming progressively weaker Soon the arm hangs loosely by the side and the leg is dragged in walking The degree of choreic paralysis bears no relation to the severity of the movements for the former may be severe, when the latter are slight and vice versa Choreic paresis is apt to return with successive attacks of chorea but not always in the same region

Limp chorea (*chorea mollis*)—This is a more severe degree of choreic paralysis which may affect the whole musculature but is more often of hemiplegic distribution It may be preceded by the usual symptoms of chorea More often the paralysis is the first noticeable symptom and this develops rapidly in from 24 to 48 hours The paralysis is characterised by complete flaccidity of the limbs, the child lies upon its back and does not move and if one of the limbs be raised from the bed and then released it falls limp and lifeless The head is no longer held in a natural position but falls round on to the ear Careful investigation however, rarely fails to reveal some slight choreic movements either in the face or in the fingers Paretic chorea and chorea mollis run a benign course and recovery is said to be almost invariable

3 INCO ORDINATION OF VOLUNTARY MOVEMENT may be the first symptom of chorea to attract attention and it may precede the appearance of the choreic move ments It may be very obvious when the movements are slight and it is mo t noticeable in those of the hand and forearm which lack precision and in those of articulation deglutition and respiration The involuntary movements that have been described are superimposed upon voluntary movements which they render inco ordinate at times interrupting them abruptly and at other times tending to prolong them

4 PSYCHICAL DISTURBANCES are common some degree of emotional instability failure of attention and depression being present in most cases and, generally in proportion to the severity of the affection The patient s behaviour changes she may laugh or weep without sufficient reason she may become capricious irritable and obstinate attention and memory are usually impaired and less interest is taken in the surroundings A condition of hebetude may develop Delirium may occur in acute and grave cases It is usually violent and loquacious and resembles other forms of toxic delirium and it is of serious prognostic import Visual hallucinations of a terrifying character may occur Mania is quite exceptional in children but it is not an uncommon complication in adolescents and adults The psychical disorders slight or severe usually disappear with the chorea and in all cases the prognosis as regards permanent mental recovery is good

The pupils are frequently dilated and may be unequal and eccentric and hippus may be present Sensibility is not impaired The sphincters are not affected The skin reflexes are normal The deep reflexes are also normal in a large proportion of cases but often the knee jerk shows an alteration which is peculiar to chorea On tapping the patellar tendon the resulting contraction of the quadriceps is unduly sustained and the leg remains in a position of extension at the top of its excursion for several tenths of a second in other cases a pendular knee jerk is present In severe cases the deep reflexes may be diminished and rarely may be absent for months

RHEUMATIC MANIFESTATIONS —Cardio vascular changes are common in chorea In nearly all the cases careful and repeated examination of the heart will reveal slight dilatation and reduplication of the second sound often with reduplication of the first sound and increased rapidity of the pulse Doubtless these are signs of

myocardial involvement resulting from the rheumatic infection Irregularity of the pulse may be dependent upon the altered rhythm of respiration Systolic murmurs are common and these may be hæmic in nature or may be the expression of cardiac dilatation but in the majority of cases they are indicative of endocarditis Endocarditis is present in 90 per cent of the fatal cases At least one half of all cases present cardiac murmurs which are suggestive of the presence of endocarditis while *some cases with no cardiac murmur during life are found post mortem to have endocarditis* The mitral valve is commonly affected lesions of the aortic valve being uncommon Pericarditis is a frequent associate of endocarditis, only in rare instances does it occur alone The valvular affections which are met with in chorea may be the result of antecedent rheumatism, or they may develop in the course of the chorea, or while no signs of endocarditis are present during the attack the patient may shortly afterwards present the signs of organic valvular disease Cutaneous affections which occur in rheumatism are met with also in chorea namely erythema purpura and subcutaneous nodules Acute articular rheumatism is comparatively rare and when it occurs it is usually accompanied by a cessation of the choreic movements When rheumatic phenomena are present and in the acute mania of chorea pyrexia is usually present but uncomplicated chorea is an apyrexial disease

RECURRENCE —One third of the subjects of chorea have more than one attack. Females are more prone to a recurrence than males in about the same proportion as they are more liable to original attacks The average interval between the attacks is 1 year If therefore a patient has remained well for 2 years it is improbable that a recurrence will take place The greater the number of choreic attacks, the more likely is the heart to be found affected and therefore cardiac complications are more often met with in recurrences In a recurrence of chorea the symptoms are usually less severe and their duration shorter than in the original attack

Course and Prognosis —The disease tends to a spontaneous termination after a variable time which is usually from 6 weeks to 6 months The duration rarely *falls short of the earlier period The average duration of cases treated in hospital* has been found to be 10 weeks Cases which last for more than 12 months are not rare and slight cases with remissions may last several years The course of the malady is that after a gradual development of symptoms there is a stationary period during which symptoms are well marked followed by a period of gradual diminution In some of the more severe cases of chorea where deglutition is difficult the patient is likely to be insufficiently fed and this constitutes a grave danger since in the condition of semi starvation so induced the chorea develops apace In such cases articulation and swallowing become impossible and the movements become ceaseless so that both rest and sleep become gravely impaired the patient wastes rapidly and is in danger of death from exhaustion unless prompt measures for restoring the depleted nutrition are taken This is the condition known as chorea gravis

The proportion of fatal cases occurring in chorea is less than 2 per cent Death is most often met with in first attacks occurring about the age of puberty and in cases associated with pregnancy It is very uncommon in young children and in recurrences of chorea

Diagnosis —The nature of the involuntary movements of chorea is usually so characteristic as to make diagnosis easy and to avoid any confusion with other maladies which present conspicuous involuntary movements *Nevertheless occasionally* a case of multiple tics in a child does present difficulties for the movements are not—as is so commonly stated—invariably repetitive In chorea the involuntary movements may lead to the dropping of objects from the hands This does not happen in the case of tics Again when the *choreic subject* gives the observer a firm and sustained handclasp, the irregular waxing and *waning* of the muscular contraction may be felt throughout by the observer In a case of *tics* the contraction is steadily maintained as in the normal subject In myoclonus the movements are short and

shock like while in athetosis they are slow and writhing In chorea mollis or hemiplegic chorea the paresis is in itself highly characteristic It is a flaccid paralysis which is never absolute and usually affects the arm most. There is no pain and no wasting and while spasticity is absent the deep reflexes are usually preserved

Treatment —It is well to commence treatment in every case with several days absolute rest in bed but in the milder cases this need not be persisted in beyond a few days though the ordinary periods of rest should be prolonged

The salicylates are of great value and of these aspirin is the most useful and it is best combined with equal doses of sodium bromide gr 10 of each may be given in mixture thrice daily after meals for a child between the ages of 8 and 14 and aspirin should be continued well into convalescence

In addition tonics such as syr ferri phos co (Parrish) and cod liver oil and malt are valuable especially in the convalescent stage

Severe cases of chorea call for skilled nursing The sides of the cot or bed should be well protected by pillows and the patient s hands and elbows covered with pads of cotton wool An unbreakable feeding cup is necessary When swallowing is difficult resort should be made to nasal feeding especially because of the importance of ample nourishment in this disease In the worst cases morphine may be required at night

HUNTINGTON S CHOREA

Synonym —Hereditary Chorea of Adults

This is a somewhat rare disease in which symptoms almost identical with those of rheumatic chorea namely involuntary spontaneous movements ataxy paresis and slow and slurring articulation gradually appear in adult life and usually about the age of 40 years and are accompanied by progressive mental failure with delusions and suicidal tendency The choreic movements are seldom severe but the inco ordination may be well marked Maniacal outbursts are not uncommon The disease always progresses slowly to a fatal termination in from 5 to 30 years and treatment is entirely unavailing It is a familial disease and the transmission is direct from parent to child but if a generation escape the malady it seems not to reappear subsequently Sporadic cases in which no heredity can be traced do however occur The sexes are equally affected Further than the heredity no causal factors are known The morbid anatomy consists in a slow progressive degeneration of the nerve cells of the basal ganglia and of the cerebral cortex with consecutive atrophy of the convolutions neuroglial overgrowth and meningeal thickening

APOPLECTIFORM CHOREA

This title has been given to rare cases of chorea of sudden onset in elderly subjects The involuntary movements are usually unilateral and are often of great severity and large amplitude (hemiballismus)

In cases of this disorder examined after death thrombotic softening or hæmorrhage has been found in the subthalamic region particularly in the corpus Luysii The mechanism by which small lesions in this situation give rise to such violent manifesta tions is not understood but the occurrence of such cases is obviously of great theoretical importance

SENILE CHOREA

A malady in which typical choreic movements constitute the chief feature is met with in elderly people and is possibly due to a progressive neuronic degeneration in those regions affected in the other forms of chorea It differs from Huntington s chorea in the late onset the absence of heredity and in the absence of mental changes

MYOCLONUS

Synonym —Paramyoclonus Multiplex (Friedreich) Myoclonus Epilepsy (Unverricht)

The characteristic symptom of this very rare condition is the occurrence of sudden shock like contractions of the muscles which may vary in intensity from simple fibrillary twitching to contraction which causes a violent movement of a limb The movements are often symmetrical, and are especially incident in the proximal muscles of the limbs

Ætiology —The malady appears in children usually between the ages of 5 and 15 years while in adults it commences between the ages of 25 and 40 years Both sexes are liable to the affection Many instances in which several children of the same parents have been affected have been recorded and in a few the malady has been transmitted through several generations There is now good pathological evidence that in some cases the condition is associated with diffuse cerebral lipoidosis and is related on the one hand to subacute inclusion body encephalitis and on the other to the various forms of cerebro macular degeneration while in other cases the peculiar bodies described by Lafora are found in the cells of the brain and also in the liver heart and possibly other organs

Symptoms —The movements of myoclonus are simple sudden movements and may exactly resemble the movement resulting from a single faradic stimulus Each movement commonly involves a single muscle only and it may concern no more than a few fibres resembling then the fibrillary twitching common in progressive muscular atrophy In other cases many muscles may be implicated in the shock like spasms which may be of so violent a nature as to throw the patient to the ground The distribution of the contraction is never determined by that of the nerve supply nor do the muscles contract according to their synergic association Myoclonic movements are irregular as regards rhythm and range of successive movements The upper limbs are more affected than the lower, and the proximal parts more than the distal while the periphery the hand and foot often escape Voluntary muscular effort usually checks the myoclonic movements but in rare instances it excites or augments the spasm The electrical excitability of the muscles is unaltered and there is no muscular wasting but the mechanical excitability of the muscles is increased and percussion of a muscle may evoke the spasms The sphincters are unaffected The reflexes both superficial and deep are normal Sensory phenomena are absent Speech may be seriously interfered with when the muscles of jaw tongue palate and larynx are implicated and spontaneous laryngeal and pharyngeal noises may occur The ocular muscles seem never to be the seat of the movements Epileptiform convulsions are present in the typical cases

Characteristic electro encephalographic changes have been recorded

Diagnosis —This is not difficult since the simple shock like movements in symmetrical muscles without any resemblance to volitional movements and entirely destitute of rhythm occur in this disease alone

Course, Duration and Prognosis —Myoclonus as a rule is a slowly progressive affection up to a certain stage and when this is reached it may remain stationary for years having little tendency to shorten life death ultimately occurring from some other disease without any period of freedom from the spasms Rarely the disease has ended fatally within a few months of the onset with progressive mental failure and coma

Recovery may take place spontaneously but the affection is very prone to recur

Treatment —Every available measure should be used to improve the general bodily condition so as to bring about a more stable condition of the nervous elements by improving their nutrition Sedatives may be tried but are seldom of value Myanesin taken by mouth relieves or abolishes the twitchings temporarily

SPASMODIC TORTICOLLIS

Definition —A disease of the nervous system characterised by tonic and clonic contraction of the superficial and deep muscles of the neck causing the head to assume either a position in which it is turned to one side and upwards or a position of marked retraction (retrocollic spasm) It is more correctly to be regarded as a disturbance of movements than of muscles and perhaps physiologically considered it may be spoken of as a disorder in the carriage of the head This carriage is a more complex and highly co ordinated function in the erect posture than in the quadru pedal posture it is a function peculiar to man and in this sense is of recent evolu tionary development. We may perhaps see in this a factor determining its frequent derangement as in spasmodic torticollis

Ætiology —The disease is most frequently met with in middle aged or elderly subjects but it may occur at any age from puberty onwards It is twice as frequent in females as in males The causation is most obscure Not infrequently neuropathic heredity such as epilepsy and insanity exists and the patients are often of highly strung nervous irritable dispositions Nervous shock prolonged anxiety and general ill health have frequently preceded the onset of symptoms Less often local strain or injury and exposure to cold have been the presumably exciting causes In a few cases it appears to develop from an occupation neurosis it developed for instance in a tailor who in drawing each stitch had the habit of making a short jerking move ment of the head to one side It occasionally occurs as a symptom of hysteria but such cases should be carefully separated from those in which there is no hysterical manifestation as being more susceptible to treatment and having less tendency to recur when once cured A torticollic movement may occur as a variety of tic. Typical torticollis may occur as the end result of lethargic encephalitis

Pathology —No morbid anatomical changes have been found On account of the involvement of several muscles, effecting special movements in this disease (as is well instanced by the over action of the frontalis in retrocollic spasm for retraction of the head is always normally associated with raising of the eyebrows in the act of looking up) it is probable that torticollis is due to disorder of those centres which direct such associated movements of the affected muscles

Symptoms —The onset is usually insidious but in rare cases may be quite sudden as in the case of a man aged 40 years who when walking along a London street suddenly turned his head at the sound of an accident which shocked him severely he was unable to turn his head back without using his hands to do so and he subsequently developed the most severe torticollis The initial symptom is always spasm which may be either tonic or clonic and frequently both forms of spasm are combined in the same case In the tonic form the head is retracted and the face turned to one side usually the left and owing to the retraction of the head the face is turned upwards The shoulder on the side to which the head is inclined is usually raised In severe cases all the muscles of the upper extremity the scaleni and the face muscles may become involved The spasm except in the earliest stages always involves muscles of both sides of the neck Where the bilateral involvement is general and equal the rotation of the head does not recur but it becomes strongly retracted and the condition is then known as retrocollic spasm Such retrocollic spasm is always accompanied by marked over action of the frontales the skin of the forehead being thrown into transverse wrinkles In the clonic variety there is jerking movement of the same muscles usually associated with some degree of tonic spasm The eyes do not follow the movements of the head in the jerkings The muscle primarily involved is the sterno mastoid the action of which is to incline the head forwards and towards the shoulder of the same side and rotate the face to the opposite side The next muscle involved is the splenius of the opposite side, which inclines

the head backwards and rotates the face towards its own side its rotatory action thus coinciding with that of the opposite sterno mastoid When the splenii of both sides act together the head is strongly retracted Next to be affected are the upper parts of the trapezii and the deep neck muscles and with further spread of the spasm any neighbouring muscles of the shoulder and upper extremity may be affected Sleep causes cessation of the clonic spasm but not always of the tonic spasm when the case is severe The spasm is always increased by fatigue and excitement. There is no wasting of the muscles involved but on the other hand they may be even hypertrophied if the spasm has existed for long and their electrical excitability may be increased The amount of pain associated with the spasm varies greatly There may be a slight feeling of cramp only but usually there is a great deal of aching pain, which may radiate down the arm and into the side of the head and make life unbearable to the patient More rarely sharp neuralgic pains are present

The course of the disease which has no tendency to shorten life is chronic exacerbations and remissions under treatment being common and recurrence, after temporary cure, frequent

Diagnosis —This is usually quite simple Fixed positions of the head associated with spasm occur in disease of the cervical spine, especially in spinal caries and are also associated with enlarged lymphatic glands in the neck The local signs of these conditions however are characteristic

Treatment —Spasmodic torticollis is a most intractable condition and in many cases temporary alleviation is all that can be secured It is usually best to begin treatment by rest in bed the patient lying supine with the head low and between sandbags or pillows The regular administration of phenobarbitone or of chloral and bromide may then be tried Many years ago Bastian claimed good and permanent results from a continuous narcosis lasting 3 weeks and induced by chloral hydrate Probably a combination of rest as above described together with massage and resistance exercises is the most useful line of treatment In some cases the application of a plaster mould fixing head and shoulders and worn for one or more months or a more easily removed and lighter metal splint will give complete respite from muscular spasm while it is worn and very occasionally permanent respite after removal In severe and disabling cases this is well worth trial Surgical measures (tenotomy excision of the sterno mastoid posterior root section) have all proved disappointing and are not to be recommended Except in cases of hysterical origin psychological treatment is without effect

There is a *congenital form of torticollis* which is of a very different nature The disease is prenatal and analogous to congenital talipes the sterno mastoid alone is affected and nearly always that of the right side Such a muscle is frequently ruptured during birth, and this has given rise to the opinion that the birth injury and subsequent hæmatoma of the muscle were responsible for the torticollis In many of these cases there is marked facial asymmetry the face being smaller on the side of the affected sterno mastoid This association points strongly to some defect in the nerve centres of the medulla Treatment consists in tenotomy of the contracted muscle

THE TICS

Synonym —Habit Spasm

Definition —A group of maladies characterised by the occurrence of (1) sudden rapid twitch like involuntary co ordinated movements always of the same nature and in the same region or of (2) sudden psychical phenomena imperative ideas and explosive utterances or (3) of a train of deliberate highly co ordinated actions produced by an imperative idea Any combination of these phenomena may occur

The tics are both ætiologically and clinically related to spasmodic torticollis into

which some of the motor tics gradate A torticollic movement may occur as a tic and it may in rare cases pass over into an established torticollis

The tics may be conveniently divided for clinical purposes into the following groups between which any combinations may occur

(1) The clinical picture is made up by the occurrence of sudden twitch like co ordinated movements which resemble reflex or defence movements The movement is always of the same nature and occurs in the same region though several different tics may occur in the same patient The usual region affected is the face with the pharynx and larynx the neck and upper extremity This form occurs chiefly in children and usually runs a favourable course—Simple Tic

2 The spasms are more severe and complicated than in simple tic and imperative ideas and explosive utterances are common and important symptoms The condition is met with soon after puberty and more commonly in males—Convulsive Tic

3 There is no spasm or other motor manifestation but the psychic tic is ex pressed by uncontrollable imperative ideas explosive utterances arithmomania etc — Psychical Tic

The tics are expressions of unrest and of embarrassment in consciousness in a nervous system which is highly sensitive and not too stable There is always the desire to relieve the embarrassment by the occurrence of the tic and a feeling of relief when it has occurred coupled often with disappointment at the failure of its sup pression

While the more simple forms of motor tic from their pattern suggest strongly that they were originally associated with some peripheral irritation from the con junctiva in the case of a blinking tic from the nose in a case of snuffling tic and from the larynx in a case of laryngeal tic and that constant irritation from these regions has set up a habit yet it cannot be too strongly pointed out that in many cases no such peripheral irritation precedes the onset of tic and the irritation and cause come from within the nervous system alone

1 SIMPLE TIC

Synonym —Habit Spasm

This is a common disorder of late childhood the majority of the cases occurring between the fifth and tenth year Both sexes are prone to the condition The onset may be preceded by deterioration of health from any cause and sometimes fright and emotion bring on the tic Often the malady arises in perfectly healthy children with out assignable cause The children are usually highly strung and intelligent It is a rare event to see a dull and backward child with a tic

Symptoms —The recurring tic appears somewhat suddenly and may reach its height in a few days The movements are of the nature of a simple act They occur *suddenly and without warning and are executed rapidly Usually the movement* is of one kind only but sometimes several movements coexist The common site of the spasm is the head face and neck Blinking winking alternate elevation and depression of the eyebrows side to side movements of the mouth tossing the chin in the air sudden movements of the tongue palate or larynx accompanied by an unpleasant fidgeting sound are of frequent occurrence while any movement of the head upon the shoulder torticollic movements shrugging of the shoulder and any movements of the arm may be met with Respiratory movements are often associated with those occurring in the tongue and larynx Tic affecting the legs is much less common The movements cease during sleep Generally a variable time of some length separates the individual movements but in severe cases these may follow one another almost unceasingly They are increased by excitement and by observation and can usually be controlled by the will but only for a limited time

Diagnosis —The movement of tic is so peculiar that it cannot be confused with

any other spontaneous involuntary movement It is the same movement repeated with very rapid execution in the same place It is short and sharp like a twitch In chorea the movements are slow compared with those of tic and are irregular in nature in time and in place

Prognosis —Most cases of simple tic recover whether they are treated or not. They recover much more quickly under treatment and 2 or 3 months suffices in most cases to see the end of them The longer a tic lasts the more difficult it is to cure In the rarest cases only does a tic of this nature persist or merge into one of the more severe forms

Treatment —A scrutiny of the general health should be made and any defects attended to Matters of hygiene diet, education, exercise and pleasure should be correct and normal Observation and remarks upon the child s defects and anything tending to increase self consciousness should be avoided The confidence of the child should be gained if possible and any source of mental worry or grief or annoy ance should be ascertained and corrected Restraint and discipline should be kindly taught, and an orderly life followed in which the child is happy, and in which his time is fully and congenially employed

2 CONVULSIVE TIC

In this malady which was first described by Gilles de la Tourette and which bears his name the same movements as are met with in simple tic occur but they are more severe and more widely spread and they may involve the whole body in spasm at one time In addition there are psychic tics which cause irresistible im pulses among which are explosive utterances repetition of words sounds and gestures, and also imperative ideas

Ætiology —The stigmata of physical and mental degeneracy are rarely absent neuropathic and sometimes direct heredity is often present The malady is said to be more common in males and is met with more often in France than in England—*where it is a rare disorder The symptoms appear usually between the ages of* 10 and 15 years and commonly follow physical or mental shocks or acute illness of any kind

Symptoms —The spasmodic movements resemble at first those of simple tic in their nature and rapidity and favour the same sites but they are not restricted to the repetition of the same movement but successive movements may vary widely *in position* and extent and sometimes involve the whole musculature of the body The great variety of facial grimaces head jerking grotesque attitudes and ridiculous pantomime which may occur in this affection lead commonly to the belief that the patient is shamming The tic is not continual as in the simple form It occurs in the form of bouts in which the same pantomime is reproduced These are often excited by observation and emotion They can often be controlled but with much *fatiguing effort on the part of the patient* who becomes so worn out with half successful efforts to control them that he ceases to make the attempt Between the attacks the patient seems quite normal The psychic phenomena are the same as in psychical tic about to be described and the treatment of the two conditions is identical

3 PSYCHICAL TIC

In this condition there is no muscular spasm but the sudden event takes the form of explosive utterances imperative ideas and impulsive acts This condition often occurs as a part of convulsive tic The exclamatory tic consists of some sound or word or group of either which is habitually uttered with complete irrelevancy of time place or sense Sometimes the words are of an obscene nature and cause the greatest distress to the patient The utterances may be single or may be repeated

over and over in rapid succession Echolalia which is an uncontrollable impulse to repeat sounds heard or to repeat words which the patient or others have just spoken may be met with The great characteristic of the condition is that though the patient desires above all other things to prevent their occurrence he cannot do so by any effort of will Other symptoms that are commonly met with in this condition are imperative ideas and impulsive acts of all sorts and in general the symptoms of a severe obsessional state

Diagnosis —Both in the convulsive and psychical tics the diagnosis is placed beyond doubt both by the nature of the movements and by the peculiarity of the psychic disturbance

Prognosis —Permanent recovery has occurred from both these conditions but such an event is rare Most of the cases follow a downward course despite treatment and many end in suicide or insanity

Treatment —General tonic treatment with change of circumstance and healthy pursuits and congenial intellectual and physical occupation are the most likely to benefit The psychiatric treatment is that of the underlying obsessional state

OCCUPATION NEUROSES

Synonyms —Craft Palsy Occupation Palsy Occupation Cramp

Definition —A peculiar malady determined by the habitual use of one set of muscles for the constant repetition of an act of short range to the exclusion of acts of wider range and acts involving a different set of muscles The symptoms are (1) local pain in the muscles concerned, (2) local spasm of the muscles (3) loss of volitional control of the range and nature of the movements and (4) weakness of the movements These symptoms may occur separately or together

Ætiology —The variety of names by which this group of disorders has been known reflects the uncertainty and change in views as to its ætiology and patho genesis Certain facts are however generally agreed (1) The disorder is apt to arise in any occupation involving rapid repetitive movements of short range by a small portion of the body especially the hand Such movements figure prominently in the occupations of manual writers typists telegraphists musicians seamstresses and many others The movements concerned are always acquired and necessitate a high degree of precision and co ordination but in the course of time become so automatic that in health they are carried out without attention and almost subcon sciously while the performer s thoughts are concentrated on other aspects of his work (2) They involve the rapid repetitive action of small groups of muscles which may thus be supposed to be subject to especial fatigue In many such occupations from 5 to 10 repetitive movements a second may be executed (3) No structural change in the cerebral cortex nervous system or muscles has ever been demonstrated (4) In the vast majority of cases the disability initially concerns only one set of stereo typed movements and the affected parts function normally in other activities even though these involve movements of comparable rapidity and skill Thus the subject of writer s cramp is able to use the hand normally for shaving eating or even for playing the piano In severe and intractable cases however other similar co ordinated movements of the hand may gradually be drawn into the ambit of the disorder especially if they concern the patient s definitive occupation (5) The first manifesta tions of the disorder are likely to make their appearance when the individual is called upon to exceed a certain level of performance or after any physical or psychological event which may lower the patient s normal level of efficiency (6) The more searching the enquiry the greater is the number of these cases that are found to show evidence of predisposition towards psychological instability In a study of telegraphist s cramp in 1927 this was estimated to be as high as 75 per cent (7) Faulty training in the

any other spontaneous involuntary movement It is the same movement repeated with very rapid execution in the same place It is short and sharp like a twitch In chorea the movements are slow compared with those of tic, and are irregular in nature in time and in place

Prognosis —Most cases of simple tic recover whether they are treated or not They recover much more quickly under treatment, and 2 or 3 months suffices in most cases to see the end of them The longer a tic lasts the more difficult it is to cure In the rarest cases only does a tic of this nature persist or merge into one of the more severe forms

Treatment —A scrutiny of the general health should be made and any defects attended to Matters of hygiene diet education exercise and pleasure should be correct and normal Observation and remarks upon the child s defects and anything tending to increase self consciousness should be avoided The confidence of the child should be gained if possible and any source of mental worry or grief or annoyance should be ascertained and corrected Restraint and discipline should be kindly taught and an orderly life followed in which the child is happy, and in which his time is fully and congenially employed

2 CONVULSIVE TIC

In this malady which was first described by Gilles de la Tourette and which bears his name the same movements as are met with in simple tic occur but they are more severe and more widely spread and they may involve the whole body in spasm at one time In addition there are *psychic tics* which cause irresistible impulses among which are explosive utterances repetition of words sounds and gestures and also imperative ideas

Ætiology —The stigmata of physical and mental degeneracy are rarely absent neuropathic and sometimes direct heredity is often present The malady is said to be more common in males and is met with more often in France than in England—where it is a rare disorder The symptoms appear usually between the ages of 10 and 15 years and commonly follow physical or mental shocks or acute illness of any kind

Symptoms —The spasmodic movements resemble at first those of simple tic in their nature and rapidity and favour the same sites but they are not restricted to the repetition of the same movement but successive movements may vary widely in position and extent and sometimes involve the whole musculature of the body The great variety of facial grimaces head jerking grotesque attitudes and ridiculous pantomime which may occur in this affection lead commonly to the belief that the patient is shamming The tic is not continual as in the simple form It occurs in the form of bouts in which the same pantomime is reproduced These are often excited by observation and emotion They can often be controlled but with much fatiguing effort on the part of the patient who becomes so worn out with half successful efforts to control them that he ceases to make the attempt Between the attacks the patient seems quite normal The psychic phenomena are the same as in psychical tic about to be described and the treatment of the two conditions is identical

3 PSYCHICAL TIC

In this condition *there is no muscular spasm* but the sudden event takes the form of explosive utterances imperative ideas and impulsive acts This condition often occurs as a part of convulsive tic The exclamatory tic consists of some sound or word or group of either which is habitually uttered with complete irrelevancy of time place or sense Sometimes the words are of an obscene nature and cause the greatest distress to the patient The utterances may be single or may be repeated

disabling fashion In a third and numerous group it progresses to incapacity, and tends to reappear with every change of occupation In a few cases the patients become incapacitated for all the finer movements of both hands The prognosis is usually serious but a correct forecast can only be made from the history and progress of each individual case

Treatment—The responsibility and costliness which the Compensation Act entails upon employers are slowly enough but surely leading to the abandonment of those instruments the manipulation of which may produce cramp Good teaching of unconstrained methods of manipulation and encouragement of ambidexterity in all the occupations concerned are important prophylactic measures Long hours and the speeding up of work should be avoided After long absence from work the work should be gradually resumed and not recommenced at full pressure When the malady appears rest and change of work afterwards are absolutely essential Long continued rest be it remembered cuts both ways for, as has been pointed out above resumption after long rest is actually a cause of cramp for long unemployment decreases the stability and the aptitude of the mechanism

General treatment consists of the removal when possible of adverse factors in the patient s environment such as uncomfortable working conditions poor light excessive noise and sources of personal friction Full attention should be given to all aspects of the subject s physical well being

Psychological treatment may play a valuable part in relieving the underlying anxiety and tension and in enabling the individual to make a better adaptation to his surroundings and whenever necessary in giving guidance as to a change in occupation Careful selection of personnel in occupations liable to the disorder is of great value in eliminating those with special predisposition to this form of breakdown

When attention has been given to these factors re education of the movements themselves can profitably be attempted particularly in the variety of the disorder most often encountered in general practice—namely writer s cramp A specially large pen or pencil should be used and held loosely and comfortably in the natural writing po ture At first the patient should practise drawing straight lines from left to right with easy movements of the forearm Next while the same basic movements are maintained the lines should be made wavy by simultaneous movements of the wrist Then the waves should be regularly interrupted so that they become series of pot hooks m s and n s From this by gradual stages the smooth execution of other letters may be achieved

LOCAL LESIONS OF THE SPINAL CORD

INTRODUCTION

For le ions of the spinal cord the general rule applies that examination of the nervous system enables us to determine the nervous structures which are affected and also the site of a lesion but in order to determine the nature of the lesion we are dependent on information obtained from other sources namely (1) the history (2) the general examination of the patient and (3) special tests

There are many morbid affections in which the spinal cord is damaged only in a short portion of its extent and it may be of the greatest importance to determine the exact site of the lesion

The functions of the motor and sensory tracts are usually to a greater or less degree interrupted by the lesion and it is possible by examination of these functions to determine the somatic level below which muscular weakness spasticity and reflex disturbances exist and below which sensory functions are impaired By these means

use of the instrument, *e g* the pen, and bad design in machinery, *e g* certain varieties of Morse transmitters predispose to the disorder in operatives concerned

Opinion has gradually moved away from the original conception that the disorder was due to structural change or uncomplicated physical fatigue towards the view that it is primarily psychogenic Causative factors are no doubt numerous and often multiple and both physical and psychological in nature but in their summation they result in the breakdown of the smooth execution of a stereotyped movement and ultimately lead to the setting up of a faulty habit closely akin to a stammer or a tic.

Symptoms —These are of two orders namely subjective consisting of dis comfort pain and the sense of fatigue and objective comprising muscular spasm and the abnormalities of movement arising from it and from the effort to avoid both pain and spasm In some subjects pain in others spasm predominates

The onset is gradual In the case of writer s cramp the movements of the pen become inexplicably difficult and tend to be irregular, the strokes extending too high or too low The subject then finds himself grasping the pen with excessive force and the correct adjustment of the finger ends becomes hard and apt to fail the index slipping off the penholder This he tries to correct by a still firmer grasp The hand then begins to ache, and feels heavy and tired With the passage of time all these symptoms increase and the writing becomes more irregular and the nib is driven more firmly into the paper which it penetrates the ink spluttering over the sheet Some tremor may develop in the limb As the condition grows worse the cramp appears more and more readily when writing is started, so that even taking the pen in the hand may evoke cramp At the same time other fine and repetitive movements of the hand may be performed with normal ease and facility The pain which in varying degree accompanies the cramp tends as the affection grows worse to spread from the small hand muscles up the limb until the whole arm and shoulder ache With variations dependant upon the details of the movements involved comparable disturbances are seen in the other varieties of the disorder

Diagnosis —From what has been said of the character of the symptoms in these forms of cramp of the mode of their production by a particular movement complex and of their occurrence in the absence of signs of organic nervous disease it seems reasonable to state that errors of diagnosis should not occur

Nevertheless errors are not infrequent and consist in the diagnosing of writer s or of telegraphist s cramp when in fact some organic affection is present Paralysis agitans with little or no tremor and post encephalitic Parkinsonism provide fruitful sources of error In the clinical picture thus presented the initial symptoms may involve the right arm and hand and at first consist in a difficulty in the normally rapid and free performance of fine movements Not unnaturally the handwriting may be affected early It becomes slow in performance spidery and progressively smaller and the effort to continue writing may be irksome and even painful The total clinical picture in such a case is made up of such small deviations from the normal that the inexperienced or careless observer may miss them and may note no more than the patient himself has noted namely that it has become difficult and un comfortable to write Amongst other organic conditions which may be encountered under the erroneous diagnosis of writer s or telegraphist s cramp may be included cervical rib any organic nervous affection which impairs fine hand movements arthritis and painful affections of muscles The general principle which underlies accuracy of diagnosis here as elsewhere is careful and systematic clinical examination

Course and Prognosis —In a young subject who shows signs of the malady during training or soon thereafter the outlook is hopeless with regard to continuance of the occupation and the progress is from bad to worse In older subjects the course varies greatly Some cases recover completely and permanently even though they continue with the occupation In others—and this class is much larger than is usually supposed—the condition of cramp becomes stationary and persists though not in

kind of movement appears in which the limbs are drawn up suddenly from time to time by an involuntary contraction of the flexor muscles—flexor spasms Further by appropriate stimulation many reflex movements can be produced in the paralysed limbs The most important of these is the flexion reflex of the lower limb This is elicited most easily by stimulating the outer border of the sole by firm pressure or a pin prick and in its complete form consists in flexion of the hip and knee dorsi-flexion of the foot and an upward movement—so called extension but physiological flexion—of the great toe When the damage to the motor tracts is slight when the limbs are rigid in extension and the movement of flexion is prevented by the hyper tonus of the extensors or when almost all reflex activity has disappeared the reflex appears in its minimal form A part of this minimal response is an extension of the great toe The normal flexor plantar response is obtained from the sole alone The pathological reflex of which the extensor response is a part, may be obtained not only from the sole but when well developed by stimulating the skin and deeper structures on any part of the lower limb In the light of this the nature of many reflexes which have been described as isolated signs of pyramidal tract disease *e g* the extensor plantar response Oppenheim s and Gordon s signs and many others become clear In all of them a stimulus is applied to some part of the lower limb and the response is a flexion reflex whose most obvious component is extension of the great toe It is unfortunate that the term extensor response is commonly used to describe a movement which is physiologically one of flexion

SENSORY TRACT DISTURBANCES

The level of the lesion may be determined approximately by ascertaining the highest point at which sensation is impaired but in general for reasons which will be given the exact site of the lesion is usually several segments higher than the level determined by this method When the two sides of the cord are affected unequally the anæsthesia is confined to one side or extends higher on one side than on the other In many instances reliance has to be placed on the disturbances of pain and tempera ture sensation and it must be borne in mind (1) that the spino thalamic tract in the antero lateral column of the cord is concerned with pain and temperature sensation on the opposite half of the body and (2) that the fibres crossing the cord to join it do so with different degrees of obliquity at different parts of the cord In the lumbo sacral enlargement the pain and temperature fibres cross slowly and in fact clinical experience suggests that they have not taken up their new position until they reach the twelfth dorsal segment In the mid dorsal region the decussation of pain and temperature fibres is complete one segment above the point of entry of the root by which they reach the cord At higher levels crossing again takes place more slowly until in the upper cervical region impulses which enter together in one root ascend through five or six segments before all of them reach the opposite side At all levels pain crosses most quickly then cold then heat and touch slowest of all

When the posterior columns of the cord are involved in the lesion loss of sense of position occurs in the feet and legs with resulting ataxia Disturbances of posterior column sensation cannot be used for localisation in the dorsal portion of the cord but in the cervical portion the disturbances of postural sense in the different fingers may be of localising value

BROWN SÉQUARD SYNDROME

When a lesion affects one half of a segment of the spinal cord it interrupts (1) the pyramidal tract conveying motor impulses for the lower limb on the same side and (2) the spino thalamic tract conveying pain and temperature impulses from the opposite side of the body below the level of the lesion and (3) the posterior column conveying sense of position impulses from the lower limb on the same side as the

the level of the lesion can be determined approximately Secondly, the motor sensory and reflex functions of the individual segments of the cord are known and from this knowledge it is possible to determine more precisely in which segments of the cord function is abolished or impaired and therefore at what precise level the lesion is situated Myelography (p 1533) may confirm the site of the lesion and gives additional information in very many cases

MOTOR TRACT DISTURBANCES—SPASTIC PARAPLEGIA

Motor symptoms —Interruption of the pyramidal tracts produces spastic weakness in parts below the lesion which when fully developed, constitutes the picture of *spastic paraplegia The clinical features are* (1) Diminution of voluntary power (2) alterations in the amount and distribution of muscle tone and in the attitude of the limbs (3) changes in the tendon and skin reflexes and (4) the occurrence of certain involuntary and reflex movements

The phenomena of spastic paraplegia have been analysed by Walshe as follows it is essential to remember that the muscles of the lower limb are divided into two distinct groups, namely the flexors and the extensors and that the muscles which dorsiflex the foot and toes are physiologically flexors while the corresponding plantar flexors are extensors In all that follows these important muscles will be grouped according to this nomenclature

1 Loss of voluntary power varies from slight weakness of one group of muscles *to complete paralysis of both limbs and depends on the degree of damage to the* pyramidal tracts It usually begins in the distal segments of the limb and is greater in the flexors than in the extensors Dorsiflexion is the earliest and remains the most severely impaired movement

2 The tone in all the muscles increases early and is greatest in the extensors Hence an early symptom is generally stiffness of the limbs especially a difficulty in flexing them If the limbs are handled passively the resistance to flexion is found to be greater than to extension It is greatest at the beginning of a passive movement and decreases suddenly in a way that has given rise to the expression clasp knife rigidity As power diminishes spasticity increases, until at length the limbs are held constantly in an attitude of complete extension This combination of weakness *and spasticity with extended lower limbs is known as* paraplegia in extension

As the damage to the cord increases and when certain extra pyramidal motor tracts are affected *the extensor muscles gradually lose their excessive tone for which* connections with the brain stem through these extra pyramidal tracts are essential while the tone in the flexor muscles which depends *on a reflex arc which is purely* spinal is retained The result is that the knee and ankle jerks which indicate tone in extensor muscles are lost while the reflexes from flexor muscles (hamstring jerks) persist At the same time in some cases the limbs are gradually drawn up by the unopposed action of the flexors This combination of weakness and spasticity with flexed lower limbs is known as ' paraplegia in flexion At first the flexed position is occasional—flexor spasms later it becomes constant but is still due entirely to excess of tone in the flexors and ultimately contractures occur in the muscles and the deformity becomes permanent

3 Exaggeration of the tendon reflexes is a constant early sign of spastic paraplegia The abdominal reflexes below the level of the lesion and the cremasteric reflexes are lost early The normal plantar reflex is also lost and is replaced by a different kind of reflex—Babinski s sign the extensor plantar response

4 While the limbs are still rigid in extension the commonest involuntary movement is a spontaneous clonus of the extensor muscles in which the whole limb trembles as it does when ankle clonus is elicited in a case with marked spasticity In the later stages when the extensor muscles are beginning to lose their tone a new

segments between the "root loss" at the affected site and the upper limit of the "tract loss" In many other cases there is a state of hyperalgesia in the segmental areas corresponding to the segment just above the lesion or to the affected segment itself if the lesion be a relatively slight one

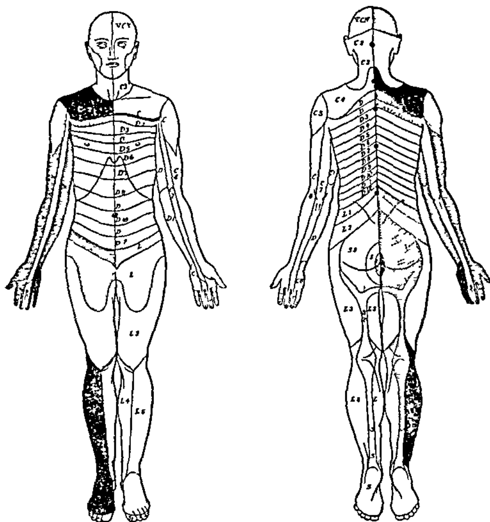

FIG 3 —Diagram of cutaneous areas of posterior nerve roots

DISTURBANCES OF THE BLADDER AND RECTUM

Emptying of the bladder is essentially a reflex function but in the normal state the reflex is voluntarily controlled being inhibited or initiated at will The detrusor musculature of the bladder wall is innervated by para sympathetic fibres from the second and third sacral segments of the spinal cord through the vesical plexus The sphincter musculature is also innervated by the sacral nerves as well as by sympathetic fibres coming from a higher level namely from the first and second lumbar seg ments with contributions from the third and fourth The emptying reflex is excited

lesion Consequently a local lesion affecting one half of the cord produces a syndrome, described by Brown Séquard, consisting of loss of power (with spasticity) on one side and loss of pain and temperature appreciation on the other side below the level of the lesion and if the posterior column is involved (and it often is not) loss of sense of position on the same side as the weakness

The Brown Séquard syndrome most commonly results from lesions in the thoracic portion of the cord Occasionally it occurs with lesions in the cervical portion, and then the upper limbs as well as the lower may be involved It does not occur with lesions in the lumbar or sacral cord because as has already been mentioned the pain and temperature fibres have not crossed in these portions and consequently with lumbar and sacral unilateral lesions all the sensory loss is on the same side as the weakness

SEGMENTAL DIAGNOSIS

Motor localisation —Each segment of the cord contains groups of anterior horn cells for several muscles and most muscles receive nerve fibres from more than one root but as each muscle seems to have one main root of supply the weakness wasting and loss of tone vary in distribution with the segment affected The muscles which suffer most when the corresponding segment is damaged are named hereunder

> C_4 *Supraspinatus infraspinatus* C_5 *Biceps deltoid brachialis supinator longus* C_6 Pronators of forearm C_7 Triceps extensors of wrist and fingers C_8 Flexors of wrist and fingers D_1 Small muscles of the hand $D_{2\,10}$ Intercostal muscles $D_{7\,12}$ Muscles of the abdominal wall $L_{2\,3}$ Adductors of thigh L_4 Abductors of thigh extensors of knee L_5 Hamstrings—Anterior tibial muscles S_1 Glutei—calf muscles S_2 Anterior tibial muscles—peronei—small muscles of foot

Wasting of the muscles in an intercostal space is a valuable guide as the muscles of each space are innervated from one segment alone If the lesion is at the level of the ninth dorsal segment the rectus abdominis is weakened below a point about an inch above the umbilicus In such a case when an attempt is made to raise the head against the resistance of a hand placed on the forehead when the patient is in the supine position the upper part contracts and the umbilicus is drawn upwards (excursion of the umbilicus) If the lesion is at the twelfth dorsal segment the entire rectus contracts but the iliac regions bulge owing to weakness of the lower part of the oblique muscles

Localisation by changes in the reflexes —Above the lesion the reflexes are normal at its level they are diminished or lost below it the skin reflexes are diminished or lost and the tendon reflexes are exaggerated The segments on which important reflexes depend are

> C_5 Biceps and supinator jerks C_6 Pronator jerks C_7 Triceps jerks $D_{7\,12}$ Abdominal reflexes L_2 Cremaster reflexes $L_{3\,4}$ Knee jerks S_1 Ankle jerks S_1 *Plantar reflexes*

In lesions involving the fifth cervical segment of the cord such as may be found in syringomyelia and in injuries associated with dislocation of the cervical spine Babinski has recorded that the supinator jerk may be abolished and replaced by finger flexion when the lower end of the radius is tapped This is known as inversion of the radial reflex and is a useful localising sign of lesions of the segment in question

Sensory localisation —The sensory areas supplied by each segment of the cord are shown in the diagrams on p 1531 Root pains in the distribution of one or more of these areas form a fairly sure guide to the affected segment There may also be sensory loss or impairment over the same areas and this may be continuous below with the sensory loss which is the result of interference with the sensory tracts or there may be an interval corresponding to the distribution of one or several

and the first sacral segment at the level of the twelfth The cord terminates just above the level of the first lumbar spine

LOCALISATION BY MYELOGRAPHY

When the existence of a compressive lesion of the cord or its exact site is in doubt great help may be obtained by injecting into the thecal canal a fluid substance which is opaque to radiography If 1 or 2 ml of Myodil or other opaque medium be injected through the occipito atlantoid ligament into the cisterna magna of the sub arachnoid space it falls rapidly to the site of obstruction where it is arrested wholly or partially and can be seen on the radiographic screen or film in relation to the vertebræ A safer procedure is to inject the Myodil by lumbar puncture and then making use of a tilting X ray table to tilt the patient so that the oil runs towards his head Even when the lesion is as high as the cervical region this manœuvre is satisfactory though some discomfort may be caused to the patient by prolonged tilting The oil will run more rapidly within the theca if it is heated to just above body temperature by immersion of the phial in warm water for 15 to 20 minutes before injection

GENERAL MANAGEMENT OF PARAPLEGIA

In all cases of severe paraplegia from spinal cord lesion in which sensory and sphincter functions are also impaired or lost whatever the nature of the lesion there are certain general principles of treatment The patient should be nursed on a fracture bed with an air water or foam rubber mattress The back should be attended to 4 hourly first washed with soap and water then carefully dried rubbed with surgical spirit or Eau de Cologne and powdered These measures harden the skin and make it less likely to break down under the constant pressure of the body-weight The patient s position should be changed at intervals of not more than 3 hours and he should be made to lie on his face for at least 6 hours in 24 in order to prevent the development of sacral bed sores When there is incontinence of urine as far as possible care should be taken to prevent the skin from becoming wet and sodden and the toilet of the anus after defæcation should be careful and thorough There are various remedies for the sacral or trochanteric bed sore when it develops Separation may be hastened by wet dressing of eusol or sometimes by fomentations though the latter should be used with caution The ulcer is packed with eusol gauze or with an ointment of zinc oxide and castor oil When it is clean and healing begins it may sometimes be hastened by dressings of gauze soaked in red lotion The heels should also be carefully watched for the appearance of the hæmorrhagic blisters which herald the development of a sore Rings for the heels may avert them and air rings for the sacrum may also be needed

Rehabilitation of the paraplegic —Experience gained during the War of 1939–1945 has gone far to improve the lot of paraplegics suffering from irreparable but solitary lesions of the spinal cord particularly young subjects with traumatic lesions

Bed sores even of large dimensions can be caused to heal by active treatment as described by Guttman Supra pubic cystotomy and tidal drainage of the bladder may gradually be replaced by the development of satisfactory automatic emptying which permits the use of a urinal Contractures and deformities can be prevented or where necessary corrected Physiotherapy and training directed to the healthy muscles may enable the patient to replace to a great extent the functions of the paralysed parts as well as overcoming the gravitational effects in the circulation which are a conspicuous feature of thoracic cord lesions

Finally occupational therapy, both prevocational and vocational in specialised spinal centres and mental readjustment can enable these patients to a remarkable degree to resume their places as active members of the community

by an appropriate degree of pressure within the bladder and it evokes a co ordinated activity combining contraction of the detrusor with relaxation of the sphincter Voluntary control over this reflex is exerted through the upper motor neurones, and as long as one pyramidal tract is functioning perfectly control of the bladder remains normal When the function of both pyramidal tracts is impaired by a spinal lesion above the lumbar region voluntary inhibition and voluntary initiation of the bladder emptying reflex become imperfect If spinal reflex activity below the level of the lesion is greatly exaggerated as for instance in many cases of disseminated sclerosis the bladder emptying reflex is hyper active and with the impaired control the patient is unable to inhibit it and precipitancy of micturition results In other instances the patient is unable to initiate the reflex when he wishes and may be able to pass urine *only after long delay* While one or other form of disturbance usually predominates they are not mutually exclusive and both may occur on different occasions in the same patient Delay in micturition may go on to retention as a progressive spinal lesion becomes more complete

With sudden or rapidly occurring tract lesions above the lumbar region associated as they are with depression of spinal reflex activity retention of urine is the rule As soon as the bladder becomes distended retention is followed by overflow incontinence and it should be an invariable rule in all cases of incontinence to feel for a distended bladder in the abdomen At a later stage in many such cases spinal reflex activity increases and reflex emptying of the bladder may then occur at intervals The bladder may act spontaneously or the reflex may be initiated by pressure on the lower abdomen or by other means Such reflex micturition is a useful aid in the management of a case of complete paraplegia but it should be realised that emptying of the bladder by this means is always incomplete and leaves a considerable amount of residual urine

With lesions in the upper lumbar region of the cord the vesical sphincter is paralysed and dribbling incontinence results Lesions in the second and third sacral segments or in the corresponding spinal roots interrupt the arc of the emptying reflex and so cause retention with a flaccid condition of the bladder wall Lesions in the conus medullaris where there is a reflex controlling centre, produce the same effect

Control of the rectum is in nearly every respect similar to that of the bladder Incontinence of fæces usually occurs only after aperients have been taken retention expresses itself as constipation and may be relieved by regular enemata

SWEATING

With severe lesions of the spinal cord sweating is excessive on the paralysed parts of the body If not evident it may be excited by cutaneous stimuli or by the injection of a small dose of pilocarpine (gr $\frac{1}{6}$) and the level of a spinal lesion may be determined by this means by an observer who is familiar with the cutaneous segmental distribution

SURFACE ANATOMY

If the cord is to be exposed at the level of the affected segments their relation to the spinous processes of the vertebræ must be known The segmental localisation of a lesion having been obtained the desired segment can be found as follows in the cervical region of the cord deduct one from the number of the segment—the sixth cervical segment is at the level of the fifth cervical spine in the upper half of the thoracic cord deduct two—the fifth thoracic segment is at the level of the third thoracic spine, and down to the first lumbar segment deduct three—the first lumbar segment is at the level of the tenth thoracic spine The remaining segments of the cord are shorter and so are farther separated from their corresponding vertebræ The third lumbar segment is approximately at the level of the eleventh dorsal spine

Localised spinal syphilis may also closely simulate intramedullary tumour but such cases are quickly recognised if the Wassermann reaction is performed on the cerebrospinal fluid and blood as a routine measure

The diagnosis between intramedullary tumour and compression of the cord from without (*e g* by a meningeal tumour or a neurofibroma) cannot usually be made with confidence on clinical grounds Search should first be made for evidence of those conditions which are known to cause compression Queckenstedt s test may of course indicate obstruction in the theca but in many cases at the stage at which diagnosis is called for it gives an indefinite result and radiographic investigation with Myodil is then required If this reveals no obstruction or if the picture obtained indicates a fusiform expansion of the cord with a little of the oil passing down at the sides of it the diagnosis of intramedullary tumour may be accepted In many cases the final diagnosis is made only by exploratory operation

Treatment —Many ependymomas have been successfully removed by skilled neuro surgeons the cord having been incised between the posterior columns If exploratory operation reveals a glioma or evidence of a hæmangioma surgery can do no more to benefit the patient and the treatment thereafter is that of paraplegia in general Radiotherapy is ineffective

COMPRESSION OF THE SPINAL CORD

In compression the lumen of the spinal canal is reduced in a small part of its length and the spinal cord is injured at this point either directly by pressure or indirectly by interference with its blood supply Nearly all the extramedullary lesions of the cord come under this heading Except in cases of collapse of a vertebral body such as may occur in malignant disease compression is in general a slow process although in a number of cases the symptoms come on rather abruptly A sudden process such as fracture dislocation of the spine causes laceration rather than compression of the cord

Clinically compression is characterised by a combination of two sets of phenomena namely, local or root symptoms in the regions supplied by the roots arising from the cord at the level of the lesion and remote or cord symptoms due to interruption of the conducting paths in the white matter Obstruction of the spinal theca may be inferred if Queckenstedt s test (see p 1378) is positive In addition complete or partial obstruction is associated with an increase of protein in the fluid below the obstruction and Froin s syndrome (see p 1379) may be present In most cases the fluid shows a slight degree of xanthochromia Radiographic examination after injection of Myodil into the theca (see p 1533) confirms or reveals the site of the obstruction and the outline of the filling defect may give a valuable clue to its nature

Compression of the spinal cord may be the result of (1) conditions arising within the theca the most important of these being meningeal tumours neurofibromata and arachnoiditis and (2) lesions compressing the theca and subsequently the cord Of the latter the most important are vertebral diseases especially tuberculous disease of the spine and secondary carcinoma also common is a protruding intervertebral disc and rarer causes are extra thecal abscess Hodgkin s disease Paget s and other forms of bone disease

I INTRATHECAL COMPRESSION

MENINGEAL TUMOURS

Though fibroma and sarcoma are occasionally found for practical purposes the meningioma or endothelioma of the dura is the only common tumour arising from the spinal meninges

TUMOURS OF THE SPINAL CORD

Synonym —Intramedullary Tumours

Ætiology and Pathology —Tumours of the spinal cord while uncommon are not rare and are encountered at all ages According to Kernohan s statistics the ependymoma a tumour arising from the cells of the ependyma of the central canal is the commonest type forming about half of the total number Tumours of this variety are demarcated from the nervous tissue of the cord, and although centrally placed are capable of surgical removal They arise most frequently in the cervico thoracic region and in the filum terminale Various types of gliomata form the remainder of the total the glioblastoma being the most common all the tumours of this group are of an invasive character devoid of any definite demarcation and therefore incapable of being removed by operation without gross damage being done to the cord In addition to the tumours arising from the tissues of the cord medulloblastomata and oligodendrogliomata may be found on the surface of the cord as seedling metastases from cerebral and especially cerebellar tumours Various types of hæmangioma are also found

Symptoms —In the case of any patient presenting the signs of a local lesion of the spinal cord of gradual onset the possibility of an intramedullary tumour should be kept in mind

The symptoms often start unilaterally, with weakness and stiffness of one leg and at a slightly later stage a partial Brown Séquard syndrome is not uncommon At all stages dissociated sensory disturbances are common on account of different degrees of involvement of sensory tracts Root pains are unusual but local muscular wasting corresponding to one or several consecutive segments is frequently present Sphincter disturbances occur at a relatively early stage

The cerebrospinal fluid contains a moderate excess of protein and some excess of globulin Queckenstedt s test does not indicate any blockage in the spinal theca until the tumour has reached such a size that it occupies most of the width of the theca Unless the tumour is at an advanced stage there may be no obstruction to the passage of Myodil and even at a late stage the obstruction may be only partial The expanding mass within the spinal theca may cause thinning of the pedicles of several consecutive vertebræ which may be apparent in the radiograph and in consequence of the thinning the interpeduncular distance on each affected vertebra is increased

Diagnosis —This has to be made from (1) other forms of spinal cord disease which produce paraplegia of gradual onset and (2) compression of the cord from without Of the former disseminated sclerosis is usually the most difficult to exclude and is the disease to which the symptoms of spinal tumour are most often wrongly attributed The diagnosis of disseminated sclerosis is rarely justified unless there is evidence of several lesions in the central nervous system and if after careful examination of the whole nervous system all the signs and symptoms can be attributed to a single spinal lesion the probability of tumour is greatly increased Secondly with tumour the exacerbations and remissions of disseminated sclerosis do not occur Finally in a case of tumour the cerebrospinal fluid may show a considerable increase of protein a moderate increase however (06 per cent or less) does not help in the differentiation It should also be borne in mind that the spinal fluid in an active case of disseminated sclerosis occasionally gives a paretic type of curve with Lange s colloidal gold test, which does not occur in the case of tumour Cases of supposed disseminated sclerosis beginning after the age of 45 especially in males should be regarded with the greatest suspicion The diagnosis may be particularly difficult in cases of hæmangioma of the cord because in many of these there is evidence of two spinal lesions

may not give rise to severe symptoms A neurofibroma may be situated partly within and partly outside the vertebral canal the constriction at the intervertebral foramen giving the tumour a dumb bell shape Histologically the intrathecal neurofibroma has a structure similar to that of the acoustic neuroma (see p 1382)

Symptoms —A neurofibroma compressing the spinal cord is apt to give rise to unilateral symptoms and to the Brown Séquard syndrome Root pains may be severe and in some cases there are spasms of intense pain on the opposite side of the body below the level of the tumour resulting from irritation of the spino thalamic tract by the growth

Diagnosis —The unilateral nature of the spinal signs may suggest the nature of the tumour Also neurofibromata cause a great increase of protein in the cerebrospinal fluid findings above 1 per cent are common in the lumbar fluid and even in the fluid above the tumour the protein content is raised The fluid withdrawn at lumbar puncture may be yellow Queckenstedt s test and examination with Myodil disclose complete or partial obstruction of the theca Radiographic examination of the spine shows in many cases enlargement of the intervertebral foramen through which the affected nerve root emerges and the Myodil picture may show the lateral situation of the obstructing mass

Prognosis and Treatment —For the solitary neurofibroma these are similar to those of a spinal meningioma When multiple neurofibromata are present the prognosis is less favourable although the removal of a single tumour may completely relieve the spinal compression

ARACHNOIDITIS

Synonym —Meningitis Serosa Circumscripta

Ætiology —As a result of a low grade inflammation of the arachnoid membrane adhesions occur within it and give rise to cystic formations containing cerebrospinal fluid or the membrane thickened and fibrous may become bound down on to the spinal cord Such arachnoiditis follows injury (perhaps as a reaction to hæmorrhage) or is a consequence of generalised infectious diseases or it may follow meningitis

Symptoms —In the course of a year or several years the cyst or contracting membrane may cause slowly increasing pressure on the cord Root pains are seldom pronounced but muscular wasting may occur corresponding to the site of the maximal local incidence of the arachnoiditis The tract signs are usually limited to gradually increasing spasticity of the lower limbs but sensory changes with a definite level may develop Pressure measurements at the time of lumbar puncture may reveal complete or partial obstruction of the theca and the Myodil picture may show an appearance of guttering the opaque fluid being broken into droplets among the arachnoid adhesions

Prognosis and Treatment —In the case of a cyst its removal by operation may bring about great improvement in the patient s clinical condition The sites of ad hesion may be difficult to see and if the cyst be opened inadvertently during operation the only evidence of its former presence is flattening of the cord and of the nerve roots at the level of the expected lesion Sometimes the position of the cyst can be inferred from the absence of normal pulsation below that level When the membranes are punctured in this position fluid escapes under pressure and the pulsations reappear Later symptoms may recur or in spite of operation they may progress as a result of the adhesive process

2 EXTRATHECAL COMPRESSION

With extrathecal compression the pressure on the spinal cord is apt to be more uniform and the manifestations have in consequence a greater tendency to be equal

Ætiology and Pathology—The meningioma is a firm oval pinkish tumour of smooth or nodular outline When impregnated with calcareous deposits the term psammoma was applied to it and it may become so calcified as to be discernible on a radiograph of the vertebral column The incidence of these tumours is mainly between 30 and 60 years of age and they affect women much more often than men Their common site is in the thoracic region and they usually lie posterior to the spinal cord

Symptoms—Pain of root distribution and of variable severity is usually the first symptom It is aggravated typically by coughing sneezing or straining This is followed after some time by spastic paralysis of slow onset and steady uninterrupted progress affecting first one leg and then the other the combination and especially the course of these symptoms being almost pathognomonic Sensory signs of similar slow course accompany the motor signs or follow them after a brief interval The sense of position may be the first to be disturbed and give rise to unsteadiness in walking and standing By the time the patient comes under observation the cerebro spinal fluid shows considerable increase in its protein content and in the globulin fraction and Queckenstedt s test is positive If the tumour is in the cervical region as is unusual all the foregoing changes are less intense

Radiographic examination may reveal an outline of the tumour at the level deter mined clinically or more often it shows some change in the shape of the pedicles of the vertebral arches or an increase of the interpeduncular distance Myodil introduced into the theca is held up and its border in contact with the obstruction displays the outlines of the surface of the tumour

Diagnosis—With such manifestations the diagnosis of meningioma is most prob able, but the diagnosis from other forms of intrathecal obstruction is not certain until the tumour is seen at operation The diagnosis from extra thecal compression is usually easier With spinal caries root pains are rarely so severe signs of bone disease are rarely absent and the paralysis is usually bilateral from the beginning and is severe by the time sensory loss develops The distinction from vertebral new growth is generally made or confirmed by radiographic examination but may for a time be impossible when bone symptoms and radiographic signs are absent

Course and Prognosis—The growth is often extremely slow Root symptoms may precede paralysis by months or even years and the weakness may increase gradually for several years before walking becomes impossible In the absence of operation it progresses eventually to complete motor sensory and sphincter paralysis possibly with paraplegia in flexion Most patients with simple tumours come to operation during the second year after the onset of the first symptom The prog nosis for recovery of power after removal of the tumour depends in part on the duration of the weakness in the lower limbs Complete recovery may be expected if it has not lasted more than a year and if sphincter control has not been lost Re covery from severe paralysis takes from 5 to 9 months When the paralysis is of longer duration recovery though gratifying is rarely complete Nevertheless full return of power has been seen after 3 years of severe paralysis

Treatment—This is obviously surgical The mortality after operation for the removal of simple tumours is low in skilled hands During the recovery stage follow ing removal of the tumour the treatment after the operation wound has healed is that of spastic paraplegia in general (p 1533)

NEUROFIBROMATA

Ætiology and Pathology—Neurofibromata within the spinal theca affect both sexes and occur mostly in early middle life They arise on the spinal nerve roots and may be solitary or multiple In cases of neurofibromatosis the occurrence of small neurofibromata on many of the lower spinal roots is the rule although they

as in other forms of tuberculosis The general condition of the patient is to be improved by fresh air, a liberal diet, cod liver oil and iron and great care is to be taken to prevent bed sores cystitis and deformities of the limbs Laminectomy is in general contraindicated and operative intervention of any kind should only be undertaken by a surgeon who has special experience of this disease After the bony disease has healed fixation of the spine by Allbee s operation or a modification thereof is called for in a few cases

TUMOURS OF THE VERTEBRAL COLUMN

Vertebral tumours are about twice as common as all the other forms of extra medullary tumours together and almost all of them are malignant Carcinoma is always secondary and is a frequent and distressing complication of cancer elsewhere A very small primary carcinoma *e g* of the breast lung thyroid or prostate may produce extensive disease of the vertebræ Evidence of compression may appear before the existence of the primary growth is suspected but on the other hand such may occur several years after complete removal of the primary growth and may even be the first evidence of a recurrence Sarcoma though the commonest form of primary growth is relatively rare and it begins in the bone or periosteum of the bodies or laminæ Primary sarcomata are sometimes multiple Secondary sarcoma arises by metastasis from sarcoma elsewhere or by direct extension from a growth in neighbouring soft parts *e g* of tumours in the mediastinal and retroperitoneal spaces

The growth of vertebral tumours is usually rapid and extensive portions of the spinal column may be completely destroyed The cord is compressed by the growth itself by displaced bone or by a process of the growth which invades the spinal canal through an intervertebral foramen As a rule the dura mater sets bounds to its inward extension Benign tumours of the spine are rare They usually grow forwards but occasionally an osteoma or an exostosis produces signs of compression

Symptoms —In most cases these are typical of spinal compression Root pains are usually severe and may be agonising but occasionally they are absent Not infrequently the onset of paraplegia is rapid paralysis developing in the course of 24 or 48 hours No deformity of the spine is ordinarily apparent but local tenderness is usual and radiographic examination reveals bony disease at a level corresponding to it Lumbar puncture reveals the signs of thecal obstruction

Diagnosis —When root pains occur in a patient with malignant disease or from whom a malignant growth has been removed the diagnosis of secondary growth in the vertebral column is most probable even though radiographic examination fails at first to reveal any deposits in the vertebral bones When pains are the first symptom mistakes are easily made because their root origin is not recognised Diminished sensibility in the painful area indicates the nature of the pain and this directs attention to the spine where tenderness or deformity is discovered As most vertebral tumours are secondary the next step is to examine the parts where carcinoma is common remembering that a small primary growth *e g* in the breast lung thyroid or prostate may give rise to widespread metastases in the bones In the absence of a history or signs of new growth in other parts the diagnosis is founded on the combination of local tenderness or deformity and rigidity of the spine with root or cord symptoms The severity of the root pains and their great aggravation by movement are characteristic

Course and Prognosis —When sarcoma or carcinoma spreads to the vertebræ from surrounding parts the duration of the disease is measured in weeks or months and death is due to the primary condition In primary sarcoma and in some cases of carcinoma of the vertebræ life may be prolonged for a year or two, and death is due rather to complications of the cord disease—bed sores cystitis etc

on the two sides especially in the lower limbs This is however, no more than a rule of thumb and there are many exceptions to it As long as the compression is relatively slight, motor tracts are more affected than sensory and consequently with the more slowly progressive conditions, weakness and spasticity of the lower limbs may precede sensory disturbances by a long period

TUBERCULOUS DISEASE OF THE SPINE

Synonyms —Spinal Caries Pott's Disease

This disease is the most frequent cause of slow compression It occurs most often in children, but is common in adults, and may begin late in life Signs of injury to the cord develop in about 1 case in 20 and are usually preceded by obvious deformity of the spine, but in many cases they appear before disease of the bone is suspected Rarely paralysis comes on for the first time in an adult who has had a curvature since childhood

The cord may be damaged by direct pressure of displaced bone, but more commonly by an abscess beneath the periosteum of the diseased vertebræ In almost all cases the injury is indirect and results from œdema of the cord arising from interference with its blood supply by tuberculous granulation tissue which forms on the outer surface of the dura mater and fills the epidural space (pachymeningitis externa) The functions of the cord may be temporarily deranged for long periods by this œdema without permanent damage to the nervous tissues hence when the disease is cured the œdema subsides and the cord recovers In cases of greater severity necrosis of the nervous structures follows thrombosis of the vessels, or prolonged pressure causes atrophy of nerve roots and complete recovery is impossible

Diagnosis —When spastic paraplegia develops in a patient who is known to suffer from tuberculosis of the spine the cause is obvious but when it precedes the appearance of signs of bone disease the diagnosis is difficult In all cases of compression the spine should be examined repeatedly for deformity tenderness and limitation of movement If tenderness is found constantly in the same place and the nervous symptoms are compatible with disease of the underlying segments disease of the bones is almost certain In young persons disease of the spine is usually caries and in adults also caries is not uncommon but tumours of the spine and aneurysm should be excluded Severe root pains are rare in spinal caries but are the rule in vertebral new growth A radiograph will usually demonstrate the presence and nature of the bone disease

Course and Prognosis —The course of the bone *disease does not always run* parallel with the paralysis and either may alter in severity independently but if the caries undergoes cure the paralysis usually diminishes Considering the severity of the paralysis the prognosis is favourable and astonishing recoveries occur *The outlook is best in young people with disease in the dorsal region* Many recover completely but more often especially in adults recovery though considerable is imperfect So long as the lower limbs remain spastic in the extended position together with exaggerated tendon reflexes the prognosis for complete recovery of power is good but if the limbs become flexed if they become flaccid if the knee and ankle jerks are lost if sensory loss is severe or if there is wasting in the limbs following damage to lower motor neurones, the outlook is bad Some patients live for years with severe paralysis but life is constantly endangered by sepsis from bed sores ascending infections of the urinary tract, chest complications and tuberculous disease in other parts

Treatment —This is to be directed towards curing the bone disease in the hope that cure of the paralysis will follow and it usually does so Complete rest on the back and fixation of the spine for many months is the routine treatment and recovery commonly takes about 2 years Streptomycin and isoniazid *should be administered*

cord is usually lacerated and its fibres are torn and its circulation interfered with so that compression if present at all plays little part in causing the persisting symptoms and its relief brings about no amelioration Dislocation of the axis however provides possible exceptions to this rule Transverse lesions of the cord may also result from gunshot wounds Secondly disruption of fibres and laceration of other elements and minute hæmorrhages occur within a localised extent of the cervical cord as a result of acute flexion of the neck The damage is probably the result of the sudden traction exerted on the cord as flexion of the neck causes the cord to be pulled up wards When the muscles of the neck are relaxed a very moderate degree of violence may cause the head to fall forward producing sudden flexion of the neck and damage to the cord With greater violence there may be accompanying dislocation or fracture of the cervical vertebræ but in the typical case the spinal cord is not compressed Sudden extension of the neck as in diving accidents also may cause severe injury of the cord with or without vertebral dislocation or fracture

Fracture dislocation of the vertebral column is most common in the region of the fifth and sixth cervical vertebræ and in the lower dorsal region Crush fractures of vertebral bodies due to force transmitted longitudinally as when a patient falls from a height and lands on his feet usually affect the first lumbar or one of the adjacent vertebræ and the corresponding lumbar spinal roots or the roots of the cauda equina may be damaged The roots being peripheral nerves are generally believed to have greater power of recovery than the structures within the cord itself

Fractures of the vertebral arches pedicles or spines may be caused particularly by gunshot wounds and in association with them the spinal cord may be injured in greater or less degree

Symptoms —A sudden transverse lesion of the spinal cord gives rise at first to a condition of spinal shock in which most of the automatic functions of that part of the cord below the level of the lesion are temporarily abolished If this occurs at a high level death is usually immediate but if not flaccid paralysis of all four limbs results If the lesion is in the dorsal region the immediate result is a state of acute flaccid paraplegia with retention of urine due to flaccid paralysis of the bladder wall (detrusor urinæ) in severe cases all the tendon reflexes and the plantar and abdominal reflexes are at first absent and there is complete loss of sensory apprecia tion below the level of the lesion In some cases the degree of spinal shock is less and the abolition of spinal function is partial

With the traction injuries of the cervical cord there is seldom the same degree of spinal shock but temporary paralysis may be considerable sensory loss is usually partial and some or all of the reflexes are preserved Retention of urine is in most instances a matter of a few hours Paralysis of the hands with relative sparing of the upper arms is not infrequent in these cases As the fifth cervical segment is often involved in the lesion the supinator jerk which depends on this segment is often abolished but the flexion reflexes remain and tapping of the supinator tendon pro duces reflex flexion of the fingers This is called inversion of the supinator reflex The fibres of the cervical sympathetic (as they descend in the cord to emerge with the first dorsal root) are often involved in the lesion and in consequence there may be contraction of the pupil and a slight degree of ptosis of the upper eyelid on one or both sides At a later stage when the lower limbs have largely recovered wasting becomes apparent in the hands and forearms and the case presents a superficial resemblance to one of amyotrophic lateral sclerosis but the history of accident, the presence of sensory disturbances and such features as the absence of the supinator jerks and signs of disturbance of the sympathetic nervous system should help to make the distinction (see p 1556)

Course and Prognosis —In incomplete and mild cases as spinal shock passes off the reflexes begin to return Retention of urine persists for a variable time and if not prevented by catheterisation overflow incontinence ensues The Babinski reflex

Treatment—In many cases of malignant vertebral disease the clinical effects of compression are relieved by extension of the spine the patient being kept flat in bed with an underlying fracture board If the paraplegia improves a plaster spinal jacket can be applied and the patient may begin to get up again In favourable cases radiotherapy may then be considered When root pains lead to the discovery of a secondary deposit in the spine in a case in which the primary growth has been removed and there is no evidence of secondary growths elsewhere in the body, radiotherapy should be employed, paraplegia is prevented the pains are relieved and life is prolonged In slowly growing primary growths of the vertebræ laminectomy is indicated in order to relieve pressure or to prevent pain by cutting sensory roots or dividing the antero lateral columns of the spinal cord The operation is merely palliative but is often followed by considerable temporary recovery

PROTRUDING INTERVERTEBRAL DISK (CERVICAL AND DORSAL)

The protrusion of an intervertebral disk in the cervical or dorsal region is much less common than in the lower lumbar region The mechanism by which it occurs is the same at all levels as a result of trauma the cartilaginous annular portion of the disk is ruptured, and the semi solid nucleus pulposus is then gradually extruded In most cases the mass is protruded backwards into the vertebral canal, and causes compression of the theca In the cervical region the degree of compression of the cord which ensues is seldom severe

The clinical history of the case is that of spastic paraplegia coming on gradually some months after an accident Progress of the paraplegia is usually slow and after a time one arm or both arms may become spastic and may show a little muscular wasting At this stage the condition in most instances becomes stationary Sensory impairment is seldom demonstrable but there is usually a zone of hyperalgesia corresponding to the segment just above the level of the lesion Mild root pains across the shoulders are likely to be attributed to rheumatism In some cases however, root pains are the principal manifestation and may be ascribed to brachial neuritis

Unless there is a close association with a definite accident the diagnosis is always a matter of great difficulty and only occasionally can it be made with confidence The spinal theca in the cervical region is wide and the degree of obstruction is not sufficient to give a positive result with Queckenstedt s test After injection of Myodil the hold up is at best partial but in favourable cases a filling defect is revealed on the radiograph While the symptoms are progressing the differentiation from an intramedullary tumour of the cervical enlargement may be impossible, but the history of an accident, and the persistent absence of objective sensory loss should raise a strong suspicion of a disk lesion, and the eventual arrest of the progress excludes the presence of a tumour From disseminated sclerosis the diagnosis may be equally difficult but if it be recognised that all the manifestations are attributable to a single spinal lesion it is unjustifiable to postulate disseminated lesions and moreover many of the patients concerned are above the age at which disseminated sclerosis is likely to begin

Some of the cases have been relieved by surgical treatment and it is only by operation that the diagnosis can be established with certainty Failing operation the sufferers remain permanently disabled but a moderate degree of spontaneous improvement is not unknown Collars of different types are often prescribed to immobilise the neck and take some of the weight of the head off the cervical vertebræ but it is doubtful whether the effects obtained compensate for the inconvenience or discomfort

INJURIES OF THE SPINAL CORD

Ætiology—The spinal cord is a delicate structure Injuries of it occur in the first place in association with fractures and dislocations of the spinal column The

of the cord and in the meninges around it and some small vessels may be thrombosed but the lesion does not appear to be primarily thrombotic (see p 1469)

Symptoms —In the non syphilitic cases there may be malaise and a slightly raised temperature and sometimes pain of " root type at the level of the lesion for a few days before the onset of paralysis These symptoms are followed by weakness of one or both legs and paralysis may be complete from the waist down within 24 or 48 hours, in other cases it is complete in an hour or two in others though remaining incomplete, it may reach its full intensity in that time, while in still other cases, the onset is apoplectic *i e* the patient feeling some weakness sits down and within a few minutes is completely paraplegic.

In the syphilitic cases pain in the back frequently precedes the onset by several hours or a day or two

If the patient is seen soon after the onset he usually shows complete motor and sensory paralysis from the waist down with flaccidity of the muscles and loss of reflexes retention of urine is present and may have gone on to overflow incontinence If some power of voluntary movement or some sensation is preserved some of the reflexes usually persist too There may be from the first a zone of hyperæsthesia at the upper limit of the paralysis, and later a girdle sensation may develop at this site While the limbs are flaccid and sensation is absent bed sores may develop with great rapidity and in the paralysed bladder intense cystitis may occur The patient may die in the acute stage as the result of these complications More often sensation and the reflexes return after a few weeks and in course of time spasticity develops in the limbs with a variable amount of voluntary power There may be a partial Brown Séquard syndrome Remarkable recovery may occur in the course of many months but even then considerable disability usually persists In other cases there is no return of power and the bedridden patient succumbs in a few months to intercurrent disease

Diagnosis —The Wassermann reaction both in the blood and in the spinal fluid should always be done with the knowledge that the latter may give a negative result in syphilitic cases even when cellular increase is present Queckenstedt s test should also be done at the time of lumbar puncture in order to exclude conditions of thecal block Poliomyelitis is excluded by the presence of severe sensory loss It may not be possible to make the differential diagnosis from hæmorrhage into the sub stance of the cord but the latter is usually associated with more pain and after the first acute stage is over with a syringomyelic type of sensory loss Angioma of the cord usually gives rise to less acute paralysis coming on with less constitutional disturbance

Treatment —The treatment consists of good nursing with the most careful attention to the bladder After the constitutional disturbance of the early days has passed massage and passive movements should be given to the paralysed limbs

In the syphilitic cases a full anti syphilitic regime should be started as soon as possible (see pp 223 1458)

LOCAL VASCULAR LESIONS OF THE SPINAL CORD

Hæmorrhage into the spinal cord is uncommon apart from pre existing vascular abnormalities When it occurs it produces signs of an acute segmental lesion followed as a rule by those of more general hæmatomyelia (see p 1549)

Local arterial thrombosis is usually due to syphilitic arteritis

In old people who are the subjects of severe atheroma transient partial paraplegia occasionally occurs most of the symptoms passing off within 24 hours or less The mechanism of its causation is not fully understood

There is some reason to think that venous thrombosis in the cord may give rise

appears and is coupled after a time with withdrawal reflexes of the lower limbs Later the tendon reflexes return and a variable degree of sensory and motor recovery may take place In severe cases this does not happen and the condition remains one of complete physiological interruption of the cord at the site of the lesion After an interval the lower limbs may become the seat of frequent flexor spasms, and a state of paraplegia in flexion may follow Any stimulus applied below the level of the lesion may then give rise to violent flexion spasms in the legs contraction of the abdominal wall and extrusion of urine from the bladder—the mass reflex" of Head and Riddoch In the great majority of those cases in which the cord is completely divided, the paralysed muscles remain entirely inert and the only evidence of reflex activity is the development of automatic function of the bladder

In severe cases the outlook is always extremely grave With high cervical lesions, death, if not immediate, may occur within a few hours from respiratory paralysis With lesions at lower levels death is liable to take place within a few weeks or months from bed sores or infection of the urinary tract The cases of less severe injuries of the cervical spine usually make good recoveries Wasting and weakness may be left in the hands, and sensory disturbances particularly of a subjective nature may persist and affect one side of the body or both sides

Treatment—Cervical dislocation should be reduced under general anæsthesia and subsequently a plaster collar should be applied to the neck in order to prevent undue mobility until the damaged ligaments have healed In cases of cervical fracture a collar should also be applied because further displacement may occur during sleep or under other conditions of muscular relaxation

In cases of fracture of the spinal column with injury of the cord open operation is usually contraindicated Fracture of the vertebral arches on the other hand may call for operation and the removal of bony fragments from the spinal canal Pressure on spinal roots is usually relieved by the Watson Jones method of treating spinal fractures

The further treatment of injuries of the spinal cord is that of acute paraplegia (see p 1533) and in no condition is the most careful nursing and skilled medical supervision more urgently called for In general the retention of urine is best treated by immediate supra pubic cystotomy but if the nursing conditions are ideal and there is good prospect of recovery tidal drainage through an indwelling catheter may be preferable The bowels are best controlled by regular enemata

ACUTE TRANSVERSE MYELITIS

Ætiology—The condition is rare during childhood and mostly occurs during the first half of adult life The sexes are affected equally In most cases the cause cannot be determined While a number are syphilitic syphilis has long ceased to be the most frequent cause

Pathology—The cord appears healthy except in a short portion of its length comprising one or two segments The lesion is most frequently situated in the lower half of the dorsal region, and at its site the cord shows intense signs of disease and may be wholly or partly diffluent In some microscopic sections of the affected segments no normal spinal tissue may be found and in others though elements are spared in an irregular fashion nearly every portion exhibits some pathological change The adjoining segments are affected in lesser degree and elsewhere the cord is healthy Unless all the elements are necrotic there is evidence of inflammatory reaction in the diseased portions There is no evidence of primary arterial or venous thrombosis but intense congestion of vessels and minute points of hæmorrhage may be present In the syphilitic cases there is intense cellular infiltration within the affected portion

OTHER DISEASES OF THE SPINAL CORD

SYRINGOMYELIA

Synonym —Status Dysraphicus

Definition —A chronic disease characterised by the formation in the spinal cord and brain stem of long cavities with surrounding gliosis To the disease in the brain stem the term syringobulbia is often applied

Ætiology —In most cases the disease begins to cause symptoms during the period of growth and it is rare for their appearance to be delayed beyond the age of 30 Both sexes may be affected and males are more prone to suffer than females There is considerable indirect evidence that the disease depends upon a congenital abnormality and other somatic abnormalities may be present in the same patient Cavitation in the spinal cord may also occur in association with intramedullary tumours with spinal vascular disease with pachymeningitis cervicalis and with hæmangiomata of the spinal cord

Pathology —At necropsy the cord is enlarged and cross section reveals a cavity filled with clear or yellowish fluid It extends up and down for many segments and the lower cervical and upper thoracic segments are the most frequently and the most severely affected The cavitation is most marked in the posterior half of the cord and appears to arise at the base of one of the posterior horns or in the middle line behind the central canal The cavity does not represent a dilated central canal for this can often be found separate from it, though the two usually communicate More than one cavity may be present It is surrounded by glial tissue which is relatively acellular and often peculiarly translucent The blood vessels frequently show degenerative changes and the fluid within the cavity may give evidence of old or recent hæmorrhage The cavity is so placed that it interrupts the crossing neurones which convey pain and temperature sensations As it enlarges the anterior horns of grey matter become involved in its surrounding gliosis and the cells degenerate Ascending and descending tracts are affected either by pressure as a result of distension of the cavity with fluid or by the glial process The posterior columns always survive longest

In the medulla the disease affects particularly the floor of the fourth ventricle in the region of the hypoglossal nucleus and tends to extend as a slit antero laterally to a position just anterior to the descending nucleus of the trigeminal nerve In its course it may destroy the motor nucleus of the vagus and glosso pharyngeal nerves or emerging fibres of these nerves The slit interrupts (1) the internal arcuate fibres passing from the cuneate and gracile nuclei to the mesial fillet and (2) the fibres from the descending nucleus of the vestibular nerve to the posterior longitudinal bundle The development of this lesion thus (1) renders complete sensory loss which was previously of the typical dissociated type and (2) causes or increases nystagmus If the slit reaches far enough it also interrupts some or all of the fibres passing from the descending trigeminal nucleus to the fillet of the opposite side and so (3) causes dissociated sensory loss on the face on the side of the lesion The disease may extend up into the pons and in rare instances higher

Symptoms —*Disturbances of sensibility* —By far the most constant and characteristic feature of syringomyelia is a sensory loss of a peculiar kind which was named by Charcot the dissociated sensory loss This is a loss of sensibility to painful impressions and to thermal stimuli while sensibility to touch to vibration to position to passive movement and to the appreciation of location upon the skin remain relatively or entirely intact In other words those forms of sensibility which travel by a path crossing in the commissures of the spinal cord are lost because the lesion of syringomyelia destroys especially the region of the commissures while these

to local lesions involving a greater or less degree of paraplegia and the residual paraplegia following local extrathecal infective conditions has been attributed to this cause

Vascular abnormalities resulting from congenital malformation of blood vessels are not very uncommon in the spinal cord The most usual type is a racemose venous angioma situated partly within the cord and partly on its posterior surface These lesions are almost always in the lower half of the cord Pain of root type affecting the lower limbs and recurring in acute episodes is a salient clinical feature It may be followed or even preceded, by wasting and weakness of one or both legs and sphincter disturbance is usually present during the acute episodes The reflex findings are often anomalous

The diagnosis is seldom made until the angioma is exposed at operation

The superficial vessels should on no account be interfered with and surgical intervention must be limited to such symptomatic measures as dividing a posterior nerve root for the relief of pain

SPINA BIFIDA

The most common developmental abnormality of the spinal cord results from a failure of the neural tube to close perfectly and to separate completely from the surface ectoderm In consequence of the failure of separation the mesodermal tissues in which the vertebral arches develop cannot close over the posterior surface of the developing cord at the affected site, and spina bifida ensues Spina bifida is thus usually associated with some abnormality in the cord itself, and its significance as a clinical finding is that it is a pointer to a local fault of development in the cord

Spina bifida is not uncommon and in 90 per cent of cases affects the lumbo sacral region and in about 5 per cent the lower cervical region There may or may not be some abnormality of the skin over the affected vertebral arches or there may be a frank meningocele Hydrocephalus may be associated Severe degrees of malformation of the spinal cord are incompatible with life

Symptoms —Weakness of the lower limbs may be present from birth or from an early age and may increase or it may be first complained of about puberty when the vertebral column elongates and the spinal cord which in these cases is often adherent at its lower end becomes pulled upon The ankle jerks and possibly also the knee jerks may be absent and the muscles of the legs poorly developed and the feet hollow Congenital talipes may be present Control over the sphincters of bladder and anus is often imperfect the former being the more frequently and con spicuously affected Trophic changes may occur on the feet and there may be areas of anæsthesia on the feet and on the buttocks *Sometimes the sensory loss is of a* dissociated type

Diagnosis —If the symptoms have been present in some degree since childhood the diagnosis is usually easy and is confirmed by radiographic examination When symptoms appear at puberty or later and there is no external abnormality spina bifida may not be thought of but if tumour is suspected radiographic investigation is likely to be undertaken and a bony abnormality is revealed which is in keeping with the clinical findings

Prognosis —In the less severe cases the symptoms become stationary and are consistent with a normal duration of life In the more severe cases which live beyond infancy the patients become bedridden and succumb at a relatively early age

Treatment —In most cases because of the malformation of the cord no im provement can be expected from operation Treatment should otherwise be symptom atic and enuresis should be treated with full doses of belladonna

paraplegia may result And again in very rare cases such pressure may lead to total avascularisation and total transverse lesion of the spinal cord with the appearance of a complete flaccid paraplegia with incontinence total sensory loss and absent deep reflexes

Sphincter trouble is usually absent or slight and occasional but in cases in which paraplegia is severe any degree may occur

The skin reflexes of the trunk are diminished or absent and the plantar reflexes are of the extensor type according to the degree of pyramidal involvement. Some degree of pes cavus is often present The knee jerks and ankle jerks are increased while the arm jerks even in the absence of muscular wasting are characteristically absent

Spinal curvature is present in many cases It consists essentially in a kyphosis or kypho scoliosis of the upper dorsal region with a compensating lordosis and lateral curve in the lumbar region The upper convexity is to the left because of the major use of the right hand It is dependent upon paralysis of the trunk muscles from involvement of the anterior horns in the upper dorsal region and in addition dys trophic changes in the bones may be factors in its production It is more marked the earlier it commences during the period of growth and in cases in which heavy manual occupation has been followed

Trophic and vasomotor disturbances —Thickening of the bones or a condition of osteoporosis and brittleness may be met with More often Charcot s arthropathy occurs It differs in no way from the similar condition in tabes dorsalis but being confined to the joints of the analgesic region it affects those of the upper extremity The most characteristic of the trophic changes consists in thickening of the sub cutaneous tissue and of the skin itself which is seen in the hands The fingers become thick and swollen and lose their natural outline the tips become blunted and the knuckle folds thick and coarse and vasomotor disturbance renders them unduly red or even blue They have been termed sausage like fingers and often stand out in contrast to the wasting of the intrinsic muscles of the hand A similar condition affecting the whole hand is common and was termed by Charcot the fleshy hand or main succulente The analgesic condition of the hands and the therman æsthesia present expose them unduly to injuries and since the injuries are likely to be unnoticed or disregarded septic infection arises easily and the results of injuries burns and whitlows are frequently seen giving rise to further deformity from scars or loss of the terminal phalanges

Considering that the efferent neurones of the cervical sympathetic system have their origin in the brain stem and their exit from the spinal cord in the upper dorsal segments thus traversing the whole of the region usually affected by the lesion of syringomyelia the frequency with which *paralysis of the cervical sympathetic* occurs is easily understood It may be complete or incomplete unilateral or bilateral and is recognised by smallness of the pupil narrowing of the palpebral aperture (sym pathetic ptosis) and a peculiar flatness of expression on the side of the face affected with decrease or loss of sweating These signs are much more obvious when unilateral than when bilateral, for in the absence of the contrast which a normal side of the face gives they are often overlooked when bilateral

Morvan s disease —This is a condition of great rarity in which a chronic peri pheral neuritis is combined with syringomyelia with consequent very severe effects upon the extremities There is absolute loss of all forms of sensibility in the hands and in some cases also in the feet together with atrophy of the intrinsic muscles The cause of this complication of syringomyelia is unknown

Diagnosis —Syringomyelia has to be differentiated in its early stages from those diseases which cause slowly progressive muscular atrophy in the upper extremities and in its later stages from other lesions of the central region of the spinal cord Those cases in which the lesions are chiefly in the ponto medullary region must be distinguished from other slowly oncoming lesions of the brain stem

forms of sensibility which travel by paths which are uncrossed in the spinal cord are not affected

The destruction of the commissures in the lower cervical and upper dorsal regions produces the dissociated sensory loss symmetrically over the thorax and upper extremities, the distribution varying with the extent of the lesion Only rarely does the symmetrical sensory loss extend below the thorax for the reason that the spinal lesion does not often extend below the mid dorsal region Occasionally the sensory loss varies in depth extent and symmetry of distribution according to the completeness, extent and symmetry of the lesion Thus in early and slight cases, the sensory disturbance may not amount to more than a relative loss of pain and temperature confined to the hands and ulnar borders of the forearms, while in an advanced case there is usually complete inability to appreciate painful and thermal stimuli over an area which would be covered by a sleeved jacket The area often extends later over the neck and the face Combinations of the "sleeved jacket" sensory loss with hemianalgesia and hemithermanæsthesia often occur in cases where both the spinal lesion and the medullary lesion are present The dissociated sensory loss makes its advent insidiously and is often unnoticed by the patient and discovered for the first time on medical examination Or it may appeal to the patient who on bathing finds that he appreciates heat and cold upon some parts of the skin and not on others Not infrequently he finds that he injures himself or burns himself without noticing it at the time

Subjective sensibility is not often affected, and for the most part syringomyelia may be described as a painless disease but there are very notable exceptions Sensations of heat and cold dull fixed pains lasting neuralgic pains and lightning pains resembling those of tabes may occur These pains are confined to the regions which are the seat of the other symptoms

Muscular atrophy —This is met with in considerably more than half the cases Though usually bilateral it is often not symmetrical and may be entirely confined to one side The intrinsic muscles of the hands and the muscles of the ulnar side of the forearms are first and most affected in the ordinary run of cases The atrophy is often here confined but it may extend up the arm though it is unusual for the whole upper limb to be affected Sometimes the shoulder muscles are first affected and again the scapulo thoracic and humero thoracic muscles may be early involved The upper intercostals and that section of the muscles which supports the spine supplied from the upper six dorsal segments suffer but the scalenes seem generally to escape The muscular atrophy is strictly limited and is apt to become complete in the muscles affected Fibrillation is not usually present The lesions of the medulla may involve the motor nuclei of the cranial nerves Wasting of the tongue on one or both sides is not uncommon and its discovery in a young subject should always arouse suspicions of the presence of syringomyelia Unilateral paralysis of the palate pharynx and all the muscles of the larynx upon the affected side may occur from involvement of the nucleus ambiguous Similarly but in much rarer cases atrophic paralysis of the face of the trigeminal muscles of the sternomastoid and trapezius may occur from unilateral involvement of the corresponding motor nuclei Nystagmus is almost a constant feature

Contractures resulting from the muscular atrophy are commonly seen in the hands and the deformity resulting tends towards the 'claw hand type but hardly reaches the degree seen in ulnar nerve paralysis and is often much modified by trophic and vasomotor changes and by the results of injuries and whitlows

Other motor symptoms —The lower extremities almost invariably escape so far as atrophy of muscles is concerned but usually present a slight spasticity with the signs of involvement of the crossed pyramidal tracts This does not often produce much disability In cases however where the lesions involve the lateral region of the cord either by direct extension or by the pressure of distended cavities severe spastic

paraplegia may result And again in very rare cases such pressure may lead to total avascularisation and total transverse lesion of the spinal cord with the appearance of a complete flaccid paraplegia with incontinence total sensory loss and absent deep reflexes

Sphincter trouble is usually absent or slight and occasional, but in cases in which paraplegia is severe any degree may occur

The skin reflexes of the trunk are diminished or absent and the plantar reflexes are of the extensor type according to the degree of pyramidal involvement. Some degree of pes cavus is often present The knee jerks and ankle jerks are increased while the arm jerks even in the absence of muscular wasting are characteristically absent

Spinal curvature is present in many cases It consists essentially in a kyphosis or kypho scoliosis of the upper dorsal region with a compensating lordosis and lateral curve in the lumbar region The upper convexity is to the left, because of the major use of the right hand It is dependent upon paralysis of the trunk muscles from involvement of the anterior horns in the upper dorsal region and in addition dys trophic changes in the bones may be factors in its production It is more marked the earlier it commences during the period of growth and in cases in which heavy manual occupation has been followed

Trophic and vasomotor disturbances —Thickening of the bones or a condition of osteoporosis and brittleness may be met with More often Charcot s arthropathy occurs It differs in no way from the similar condition in tabes dorsalis but being confined to the joints of the analgesic region it affects those of the upper extremity The most characteristic of the trophic changes consists in thickening of the sub cutaneous tissue and of the skin itself which is seen in the hands The fingers become thick and swollen and lose their natural outline the tips become blunted and the knuckle folds thick and coarse and vasomotor disturbance renders them unduly red or even blue They have been termed sausage like fingers and often stand out in contrast to the wasting of the intrinsic muscles of the hand A similar condition affecting the whole hand is common and was termed by Charcot the fleshy hand or main succulente The analgesic condition of the hands and the therman æsthesia present expose them unduly to injuries and since the injuries are likely to be unnoticed or disregarded septic infection arise easily and the results of injuries burns and whitlows are frequently seen giving rise to further deformity from scars or loss of the terminal phalanges

Considering that the efferent neurones of the cervical sympathetic system have their origin in the brain stem, and their exit from the spinal cord in the upper dorsal segments thus traversing the whole of the region usually affected by the lesion of syringomyelia the frequency with which *paralysis of the cervical sympathetic* occurs is easily understood It may be complete or incomplete unilateral or bilateral and is recognised by smallness of the pupil narrowing of the palpebral aperture (sym pathetic ptosis) and a peculiar flatness of expression on the side of the face affected with decrease or loss of sweating These signs are much more obvious when unilateral than when bilateral for in the absence of the contrast which a normal side of the face gives they are often overlooked when bilateral

Morvan s disease —This is a condition of great rarity in which a chronic peri pheral neuritis is combined with syringomyelia with consequent very severe effects upon the extremities There is absolute loss of all forms of sensibility in the hands and in some cases also in the feet together with atrophy of the intrinsic muscles The cause of this complication of syringomyelia is unknown

Diagnosis —Syringomyelia has to be differentiated in its early stages from those diseases which cause slowly progressive muscular atrophy in the upper extremities and in its later stages from other lesions of the central region of the spinal cord Those cases in which the lesions are chiefly in the ponto medullary region must be distinguished from other slowly oncoming lesions of the brain stem

The age of onset during the later years of childhood and the earlier years of adult life is *important* and during this period slowly developing paralysis with sensory loss and with or without muscular atrophy should always suggest the possibility of *syringomyelia* Other causes which may produce this system group and which may be confused with syringomyelia are local lesions of the brachial plexus and especially the lesion produced by the presence of cervical ribs root lesions lesions of the central grey matter of the spinal cord, especially central tumours of the spinal cord, and hæmatomyelia That the peculiar sensory changes of syringomyelia are usually the first signs of that disease is important, but this rule has many exceptions both as to the nature of the sensory changes and as to their time of appearance When sensory changes are not an early sign the diagnosis has to be made from such diseases as progressive muscular atrophy, peroneal atrophy and myotonia atrophica

Local lesions of the peripheral nerves produce signs which are confined to the distribution of the nerve involved the sensory loss is to all forms of sensibility, and the condition is ordinarily unilateral While these features are sufficient to distinguish such lesions from syringomyelia in nearly all cases, nevertheless in certain rare instances of syringomyelia the sensory loss and the muscular atrophy may be so narrowly confined to the distribution of the ulnar nerve as to cause close resemblance between the two conditions Any sensory loss over the trunk or signs outside the distribution of the peripheral nerve will if present, clearly divide the two conditions

Cervical ribs may produce slowly progressive atrophy of muscles pains and sensory loss very difficult to distinguish from those resulting from syringomyelia The diagnosis in these cases is beset with peculiar difficulties for so frequently do cervical ribs produce no nervous symptoms at all that their presence when demonstrated does not argue that they are the cause of the symptoms Again cervical ribs are among the commonest of the developmental peculiarities which are so frequently seen in the subjects of syringomyelia Slow muscular atrophy and slowly oncoming sensory loss and perhaps pain characterise both syringomyelia and cervical rib paralysis and the distribution may be unilateral or bilateral in either condition, but it is only when the manifestations are strictly confined to the upper extremities and neck that difficulty arises The slightest physical sign outside of this region at once turns the diagnosis in favour of syringomyelia and of these signs cervical sympathetic paralysis sensory loss on the trunk and alteration of the abdominal and plantar reflexes are the most important A very careful search must be made for any such signs and the patient observed over a considerable time before a certain diagnosis is made

Lesions of the central grey matter of the spinal cord may produce a symptom complex closely resembling that of syringomyelia Central tumours of the spinal cord when of slow growth are hardly distinguishable inasmuch as the lesion of syringomyelia is in reality a central tumour of the cord The majority of central tumours however are of more rapid development and speedily produce severe paraplegia

Progressive muscular atrophy in its early stages may cause difficulty in diagnosis since the muscular atrophy in syringomyelia may occasionally precede the appearance of any sensory loss or may be well marked when the sensory loss is slight In this connection widely distributed fibrillation is of great importance in indicating a diagnosis of progressive muscular atrophy particularly if it be seen in muscles not conspicuously wasted In peroneal atrophy the atrophy of the intrinsic hand muscles is always preceded by a more extensive atrophy of the muscles below the knee which are rarely atrophied in syringomyelia

Syringomyelia of the brain stem (syringobulbia) may be distinguished from other lesions of this region by its insidious onset and the special tendency to the involvement of the lateral region of the medulla so giving rise to a unilateral paralysis of palate pharynx and larynx with hemianalgesia and hemithermanæsthesia on part

of the face and even on the opposite half of the body Often some signs of cervical syringomyelia coexist but the medullary lesion may exist alone and it cannot be too prominently borne in mind that any very slowly progressive lesion of the brain-stem of insidious onset may be of the nature of syringomyelia

Course and Duration—The malady commencing insidiously progresses very slowly, and often ceases to progress for periods which may amount to many years The tendency to the destruction of life is not great, but when rapid extension of the physical signs and especially of paralysis and muscular atrophy of the upper extremities and respiratory muscles occurs the end is likely to come quickly Signs of great distension of the cavities such as pain and rigidity of the neck and also severe and increasing paraplegia with sensory loss of all forms of sensibility below the level of the lesion point to a rapidly fatal termination In rare instances acute exacerbations of the manifestations occur and are followed by partial remissions Such episodes are due to hæmorrhage into the syringomyelic cavity and when death has occurred in the course of one of them the cavity has been found filled with blood

It is not unusual to meet with well marked cases in which the signs develop and increase during late childhood and early adult life, and then remain more or less in a stationary condition allowing an occupation to be followed until well after middle life has been reached, but with the advent of the degenerative period of life from 45 years onwards, there is often a slow increase of the disability which puts an end to useful capacity The patients succumb to intercurrent disease, and few reach the age of 60 years

Prognosis—Recovery never occurs but arrest of the disease for long periods is frequent Those disabilities which are the result of pressure or distension may abate spontaneously or as the result of treatment and in arrested cases training may bring about lessening of the disability Increasing symptoms especially if the increase be rapid are always a cause for anxiety and increasing involvement of the respiratory muscles is the gravest of events

Treatment—In the vast majority of cases nothing can be done to retard the slow but relentless progress of the disease and treatment is therefore symptomatic. Radio therapy has been used and occasionally diminishes the spontaneous pains Rarely the presence of a dilated cystic cord may justify surgical operation and evacuation of the cyst.

HÆMATOMYELIA

Synonym—Spontaneous Hæmatomyelia

Ætiology and Pathology—Hæmatomyelia or hæmorrhage into the spinal cord sufficient to cause symptoms is a rare disease It appears to arise almost exclusively when there is some abnormality of the spinal vessels and in particular some variety of angioma excessively rarely it is associated with syphilitic disease of the spinal arteries and equally rarely with hæmophilia Hæmorrhage may occur into a syringo myelic cavity The hæmorrhage is nearly always centrally situated and shows a strong tendency to spread longitudinally and may extend over many segments

Males are affected far more often than females and the main incidence is in the first half of adult life

The clinical effects resulting from trauma of the cervical cord have in the past often been attributed to hæmatomyelia and may be due to this cause but it is now known that in the majority of such cases no significant hæmatomyelia is present

Symptoms—Prodromal symptoms may occur in the form of local weakness or transitory sensory disturbances In most cases the actual onset is sudden and the symptoms attain a considerable severity in the course of a few minutes but they may continue to increase for an hour or two

The *symptoms vary according to the site* and the extent of the extravasation In the majority of cases at first there is paraplegia with more or less complete motor and sensory paralysis up to the level of the lesion and usually with pain at the upper limit of the disturbance As the hæmorrhage extends longitudinally these manifesta tions are quickly followed by a syringomyelic type of sensory loss

Sometimes but not usually blood is found in the cerebrospinal fluid

Diagnosis —The diagnosis of primary hæmatomyelia rests upon the sudden onset, the rapid development of symptoms, which soon come to a standstill, and the physical signs of a central lesion of the spinal cord The distinction has to be made from acute myelitis Acute myelitis though rapid in onset rarely shows the sudden development of symptoms seen in hæmatomyelia, and the sensory loss which accompanies it is *not of the syringomyelic type* Prodromata often precede the onset in both conditions

Prognosis —Hæmorrhage in the cervical region may be rapidly fatal from respira tory paralysis In the non fatal cases a variable degree of recovery occurs and in many a syringomyelic type of dissociated sensory impairment ensues the intensity of the loss being usually less than in syringomyelia

Treatment —The general treatment is that of any severe spinal cord lesion with paraplegia Absolute rest is essential When there is evidence that a syphilitic lesion of the spinal arteries is in question the treatment is that of spinal syphilis Angioma and other malformations of the spinal vessels are not amenable to surgical intervention

SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD

Definition —A progressive disease associated with pernicious anæmia in which the white matter of the spinal cord degenerates the incidence of the lesions being particularly on the posterior and the lateral columns

Ætiology —It has now been determined that when subacute combined degenera tion occurs pernicious anæmia is always present in some degree but the degree of anæmia is extremely variable The spinal affection is evidently not the result of the anæmia but the spinal disease and the blood disease are both due to the absence of an essential factor now identified as cyanocobalamin (Vitamin B_{12}) both are associated *with complete gastric achylia*

As in the case of pernicious anæmia familial incidence has been recorded First met with in the third decade of life the malady in former times became increasingly frequent until a maximum incidence occurring in the sixth decade while cases com mencing in the seventh decade were not uncommon Owing to the earlier recognition and adequate treatment of pernicious anæmia the condition is becoming increasingly rare in this country

The cases seen are often atypical and may occur in patients with Addisonian anæmia in whom the treatment has been inadequate The sexes are equally affected

Pathology —The pathological and clinical features of the disease were estab lished in a classical paper by Russell Batten and Collier published in 1900 The essential lesion is degeneration of the myelin sheaths and subsequent degeneration of the axis cylinders in the posterior and lateral columns Similar degenerative changes are found in the peripheral nerves The myelin swells and later disintegrates This change first occurs in the lower dorsal region of the cord and is first seen in the centre of both posterior columns and soon afterwards in the centre of either lateral column as small areas of a darker and more translucent appearance than the normal white matter It is only at an early stage of the disease that the anatomical picture is strictly one of posterior and lateral degenerations for soon after spots of degeneration appear on either side of the anterior median fissure and in other parts of the antero lateral columns The degenerated areas increase in size centrifugally

coalesce with one another reach the surface of the cord and eventually involve the whole of the white matter of the cord as seen in transverse section with the exception of the narrow zone of short internuncial fibres which everywhere clothe the grey matter Occasionally the disease is confined to the posterior columns

From its starting point in the lower dorsal region the degeneration spreads upwards and downwards in the white columns of the spinal cord by means of the occurrence of small isolated spots of degeneration in the posterior lateral and antero lateral columns which increase in size and thus join the area previously degenerated The degeneration tends to extend upwards indefinitely and in severe and advanced cases has been found in the pyramidal tract as high as the internal capsule

The lesions of the white columns entail the usual secondary degeneration both ascending and descending but these occur late and are often much less obvious than might be expected from the severity of the local lesions The destruction of the axons by the local lesions also causes a series of retrograde changes in the corresponding nerve cells and tigrolysis vacuolation shrinking and neurophagy may be conspicuous especially in the cells of Clarke s column and in the cells of Betz which give origin to the pyramidal fibres There is never any inflammatory exudate and a peculiar feature is the absence in untreated cases of any glial proliferation

When degeneration in the peripheral nerves is severe the muscles are conspicuously wasted in the later stages and the muscle fibres show great diminution in size and poor striation There is not any considerable increase of the muscle nuclei and little or no fibrosis is found

The blood —Usually the blood shows a hyperchromic anæmia of varying severity the hæmoglobin ranges from 35 to 75 per cent the lower of these figures being common the colour index is above the normal and may be as high as 1 6 Macrocytosis is present Anisocytosis poikilocytosis and polychromasia are common Normoblasts are often numerous and megaloblasts may be found in numbers In a few instances anæmia has been absent throughout the hæmoglobin content and the cytology being normal this has occurred chiefly in cases which have run an acute and fatal course in a few months Sternal puncture shows a megaloblastic marrow A relative lymphocytosis is almost always present and may reach as much as 55 per cent This change occurs early and is helpful in the confirmation of the diagnosis of the nervous disease Achlorhydria is always present in the stomach even after the administration of histamine

A careful investigation of the blood changes at various stages of the disease and of the post mortem findings in a large series of cases has proved beyond any possible doubt that the blood changes in subacute combined degeneration are identical with those met with in the various stages of pernicious anæmia. The cerebrospinal fluid is normal

Symptoms —(1) *Nervous* —In a large majority of instances the symptoms appear insidiously and without any recognised exciting cause Sometimes the onset is more rapid and may be preceded by gastro intestinal symptoms or the patient may go to bed for a few days with an attack of influenza and on getting up again may be grossly unsteady

The first nervous symptom is usually numbness or tingling in the feet and if the patient is asked he will usually admit that he has a slight sensation of the same kind in the fingers Less often the sensation in the feet is one of swelling or coldness or as if walking on cotton wool and in a few cases unsteadiness in walking is at first the only complaint Very soon weakness in the legs is experienced and the numbness gradually spreads farther up and the patient begins to feel unsteady in walking

Examination at this time reveals a slight degree of weakness in movement of the toes or in dorsiflexion of the feet diminution or absence of the ankle jerk probably an extensor plantar reflex and a variable degree of sensory loss, the latter is usually

most marked for vibration and for sense of position in the toes and then for light touch There may be some tenderness of the feet or calves Romberg's sign is positive The superficial sensory loss is at first only over the feet then it spreads up to cover a 'sock' area and later has a 'stocking' distribution pain and temperature impairment meanwhile being added to it Loss of deep sensation however generally predominates, and unsteadiness may be very pronounced at a time when other signs are slight or absent At the stage we are referring to there are usually no objective disturbances in the upper limbs although intense numbness in the hands may be complained of

If the condition is allowed to progress, either the signs of peripheral nerve disease or those of spinal cord disease may predominate In the former case the knee jerks become diminished and the ankle jerks lost the muscles below the knees become paralysed and flaccid and eventually waste, deep sensory loss is severe and there is loss of all forms of superficial sensation over a 'stocking' area The paralysed muscles become very tender flexion spasms may set in and every movement is agonising In the upper limbs a variable degree of sensory loss may develop with astereognosis in the hands and loss of superficial sensation over a 'glove' area. The supinator jerks may be abolished but rarely the biceps and triceps jerks If the signs of spinal cord disease predominate the legs tend to become spastic, the knee jerks are exaggerated but the ankle jerks are usually weak and the plantar reflexes are strongly extensor Sensory loss is less marked as a rule than when the signs of peripheral disease predominate but deep sensation is always greatly impaired and as time goes on there is considerable loss of pain and temperature appreciation extending over the lower limbs and to a gradually higher level on the trunk In the arms the tendon jerks may be increased Except in advanced cases sphincter disturbances are slight

The cranial nerve functions are usually unaffected but optic atrophy is an important complication which occurs in a small percentage of cases and the visual disturbances due to it may be the first symptom Slight nystagmus is common

Mental changes occur in a small proportion of cases at a time when the degree of anæmia is not sufficient to account for them Apathy mild dementia and confusional psychosis with impaired memory and disorientation are the commonest types of disturbance

(2) *Anæmia* —Although anæmia is one of the most characteristic features of subacute combined degeneration since it is found in every case of long duration at some time or other and moreover it is sufficiently striking as at once to suggest the diagnosis in at least two thirds of all the patients when they first come under observation for nervous symptoms yet it may be absent throughout the course of the disease in a rapid case and its appearance may be delayed until several years after the disease of the nervous system is manifest The anæmia in almost every case is identical in every respect with pernicious anæmia Of those cases in which the blood picture is not typical nearly all show megalocytosis with a relative lymphocytosis and a high colour index as do early cases of pernicious anæmia and it may be said with certainty that the longer the patient survives the greater the likelihood of typical pernicious anæmia developing The spleen has been found to be enlarged in many cases and the marrow of the bones is typical of pernicious anæmia as may be also the iron reaction in the liver and the changes in the myocardium and other muscles As in pernicious anæmia the tongue is clean and glazed and this occurs so regularly that any appearance of furring of the tongue may justly be said to exclude the diagnosis of this disease a history of soreness of the tongue is obtained if enquired for in more than half the cases Fractional test meals show an absolute achlorhydria as in pernicious anæmia The colour of the skin is often peculiar and striking even when anæmia is not severe and is best described as 'biscuit coloured' A bright malar flush upon this yellowish biscuit coloured background gives a characteristic

and vivid facial aspect in the earlier stages of many of the cases The manifestations common to all anæmic states breathlessness headache cardiac and venous murmurs and œdema are commonly present but hæmorrhages are infrequent Syncopal attacks may occur Attacks of diarrhœa are common but on the other hand, constipation may be obstinate Irregular pyrexia is almost invariably present at some period in the course of the disease and this quite apart from fever producing complications such as cystitis and bed sores In the later stages progressive emaciation is constant and if life be prolonged it becomes extreme

Diagnosis—In the early stages of the disease when peripheral paræsthesiæ dominate the picture the condition has to be distinguished from peripheral neuritis and occasionally from peripheral arterial disease In the well developed stages of the disease its recognition presents no great difficulty Attention is quickly attracted by the conspicuous anæmia and biscuit coloured skin Following a period of slight paraplegia the steadily increasing paralysis of the lower extremities producing complete and lasting helplessness the characteristic distribution of the sensory loss the irregular pyrexia the anæmia and the relatively late onset of sphincter trouble serve to separate this disease from other forms of paraplegia The change from the spastic to the flaccid type of paraplegia with loss of the deep reflexes and persistence of the extensor response which occurs in some of the cases in the late stages, is highly characteristic

In the earliest stages and before the appearance of any definite evidence of organic spinal disease there may be such disability as to suggest hysterical paraplegia or ataxia and only the examination of the blood may expose the real disease When there is evidence of organic spinal disease it is especially from disseminated sclerosis spinal tumour tabes dorsalis and polyneuritis that the diagnosis has to be made The preponderance of peripheral subjective sensations and the anæmic appearance should always suggest a diagnosis of subacute combined degeneration Slight spastic ataxia is the common clinical picture of subacute combined degeneration of disseminated sclerosis and of spinal tumour The presence of objective peripheral sensory loss is in favour of subacute combined degeneration whereas diplopia nystagmus transient amblyopia and intention tremor are strongly in favour of disseminated sclerosis Spinal tumour is especially distinguished by a sharp line of sensory loss transverse to the axis of the body which does not spread up from below in slow fashion

When subacute combined degeneration commences with flaccid ataxia and loss of deep reflexes the distinction must be made from tabes dorsalis The extensor plantar reflex which is almost always present in the former disease and which is rare in early tabes the different distribution of the sensory loss in the two diseases the loss of power and associated anæmia in subacute combined degeneration and the results of the examination of the blood and cerebrospinal fluid for syphilitic reactions and of the latter fluid for lymphocytosis are important aids in the differential diagnosis

It is also necessary to bear in mind the strikingly close resemblance the disease we are considering may bear to polyneuritis The differentiation may in the early stages depend chiefly if not wholly upon the examination of the blood and the result of a fractional test meal But sooner or later the appearance of an extensor response will indicate the presence of a cord lesion On the other hand in the spastic type the presence of muscular tenderness in the legs is a strong indication in favour of subacute combined degeneration

Course and Prognosis—Before the days of effective treatment the duration of the disease varied within wide limits In some the progress was rapidly downhill survival being a matter of months from the first recognition of the symptoms in others the disease remained for several years in a relatively mild stage and partial remissions were common but once the patient became bedridden the survival period was usually short

With the advent of liver therapy for pernicious anæmia the outlook for subacute combined degeneration was not at first greatly changed but with more potent liver preparations and the development of an adequate technique of treatment, improvement and, later cure soon became apparent For the case that comes under intensive treatment before the patient has become quite unable to walk functional cure usually takes about 6 months to a year Some reflex abnormalities which mean nothing to the patient may still persist for a time or permanently Some authorities believe that cases of the flaccid type, in which the element of peripheral neuritis predominates, respond better to treatment than do those that are more spastic, the disease in the latter being chiefly in the spinal cord No such generalisation can however be made and in cases of the latter type the extensor plantar reflex usually the most persistent sign of spasticity may disappear Advanced cases of both types may fail to show much response to treatment But no case however advanced when first recognised, should be deprived of full treatment on this ground, and the most surprising recoveries are sometimes seen If treatment is stopped relapse occurs sooner or later, and with renewed treatment recovery again ensues but it is doubtful whether this process can be frequently repeated on account of the probability of gliosis in the spinal cord

Treatment —Whatever the degree of anæmia present intensive replacement treatment is essential Cyanocobalamin (Vitamin B_{12}) has now for practical purposes superseded the various forms of liver concentrates For the first month this should be given in doses of 100 microgrammes on alternate days Thereafter the dosage may be very gradually reduced provided that the blood picture is satisfactory and the ultimate maintenance dose may be as little as 100 microgrammes monthly The blood count should be brought up as quickly as possible to five and a half million red cells per cubic millimetre and kept at that level The more advanced the stage of the disease the more prolonged will need to be the period of intensive treatment and the more severe the residual disability is likely to be

Any suppurative condition of the body should be energetically treated Every care should be taken to prevent bed sores and cystitis When present these are often amenable to treatment in the early stages of the disease and also in less acute cases but in the later stages and in the more acute cases they are inevitable and the bodily vitality is too low for any reparative process to take place Pains are relieved by such analgesics as aspirin acetanilide amidopyrine and phenazone Flexor spasms are among the most troublesome of the symptoms since their frequent occurrence denies sleep to the patient and they are most important factors in the occurrence of bed sores The remedy which seems to have most effect in checking these spasms is barbitone

PROGRESSIVE MUSCULAR ATROPHY

Synonyms —Motor Neurone Disease Amyotrophic Lateral Sclerosis

Definition —It is usual to describe together a large group of cases in which progressive wasting of the musculature of the body and a moderate degree of spasticity are associated with and evidently secondary to widespread degenerative changes in the central nervous system the chief incidence of which is on the lower and upper motor neurones Clinically the cases are capable of great variety according to the sites of the initial wasting and the degree of spasticity but they are nearly all comprised by three clinical types In the first and most common type the wasting begins in the upper limbs and the lower limbs become spastic but do not waste This variety was called by Charcot *amyotrophic lateral sclerosis* In the second type the wasting commences in the muscles innervated from the medulla and pons and the names *progressive bulbar paralysis* and *labio glosso pharyngeal paralysis* are applied to it In the third type the wasting begins in or quickly spreads to the lower limbs and no

spasticity develops this is called the *purely atrophic type* Transitions between these types may be met with and the first two are frequently combined

Ætiology—The disease is rare before the age of 25 but occurs at all ages there after attaining its maximum incidence between 30 and 45 Males are affected much more frequently than females No causal factors have been discovered The patho logical findings are most in accord with the suggestion that the malady is due to a deficiency of some element essential to the nutrition of the spinal cord in the same sense that subacute combined degeneration and pellagra are the results of such deficiencies The question of the relation of trauma to the causation of progressive muscular atrophy admits of no decisive answer In occasional instances the onset follows more or less closely on an injury but we know of no pathological process whereby a peripheral injury can set up a diffuse degenerative process within the central nervous system Injury of the cervical portion of the spinal cord may produce a syndrome embracing wasting in the upper limbs and spasticity in the lower limbs (see p 1541) thus superficially resembling amyotrophic lateral sclerosis but there is not sufficient evidence that trauma can cause the progressive and ultimately fatal malady of which true amyotrophic lateral sclerosis is the most common clinical variety (see Diagnosis p 1560)

In rare instances progressive muscular atrophy has been described in the subjects of old acute anterior poliomyelitis Certain cases of syphilitic amyotrophy (see p 1470) present clinically a close resemblance to amyotrophic lateral sclerosis

Pathology—While in the less advanced cases the degenerative changes are almost limited to the anterior horn cells and the pyramidal tracts in the most advanced they affect almost all the structures of the cord with two striking exceptions namely the fibres of the posterior columns and the fine fibres passing forward in the grey matter It will be noted that the former fibres and probably the latter also have their cell bodies outside the central nervous system The latter probably subserve reflexes their preservation seems to be constant in amyotrophic lateral sclerosis and *not in other forms of progressive muscular atrophy and it is probably to be* correlated with the preservation of the tendon reflexes in the wasting muscles which is a peculiar and striking clinical feature of amyotrophic lateral sclerosis

To the naked eye a cross section of the spinal cord may show some diminution in size of the ventral horns The essential lesion is a primary degeneration of the cells in the ventral horns of the spinal cord and in the homologous motor nuclei of the brain stem namely the hypoglossal facial trigeminal and oculo motor nuclei Coupled with the degeneration of the lower motor neurones is a degeneration of the upper motor neurones of the pyramidal system In the ventral horn cells the degenera tion is evidenced by a gradual shrinking in size of the cells which lose their dendrites and become oval or spherical in shape The Nissl bodies slowly disappear and only in rare and rapid cases is definite chromatolysis seen The nuclei dwindle and become irregular and distorted

The dorsal and lateral horns are almost invariably intact but degenerative changes are sometimes seen in the cells of Clarke s column The affection of the motor nuclei of the brain stem in the bulbar cases is in every way similar to that of the ventral horns The degeneration of the motor nerves which take origin from the degenerate ventral horn cells often proceeds *pari passu* with the degeneration of the cells but in some cases this is conspicuously not so

The affected muscles are soft and toneless and the muscle fibres are found irregu larly degenerated bundles of normal and of degenerating fibres being found side by side until the atrophy is complete The characteristic change is shrinkage of the affected fibre to a calibre much less than normal As is usual in all slow tissue de- generations fibrosis and local arterial disease accompany the atrophy of the muscle fibres

The pyramidal neurones (cells of Betz) which characterise the precentral cortex undergo a degeneration very similar to that of the ventral horn cells but with this

difference that the earliest structural changes are found in the most distal part of the pyramidal fibres The degeneration of the upper motor neurones never proceeds to the complete destruction of anything like all the pyramidal fibres Degenerative changes are constantly present also in the anterior columns of the spinal cord

The pathological picture, therefore of progressive muscular atrophy is a widely scattered degeneration of nervous elements, not confined to the motor systems though these are predominantly affected

Symptoms—The onset is in most cases very gradual, but it may be more rapid and severe incapacity may result in the course of a few months In rarer cases, a severe degree of paralysis may develop in the course of a few days and in such cases it is not uncommon to see the most remarkable temporary improvement The nature of the onset as a rule, indicates the course which the malady will pursue A very slow onset is followed by a very slowly advancing disease often interrupted by long stationary periods whereas the more rapid the commencement the quicker will be the advance and the sooner will a fatal issue occur Accompanying and sometimes preceding the onset and not infrequently conspicuous during the early states of the disease, are certain sensory symptoms which from the confusion in diagnosis they may cause and from the scant attention which has been paid them in descriptions of the malady hitherto, deserve emphasis These symptoms are confined to the regions where the wasting first appears and consist in a subjective feeling of stiffness and uselessness much increased when the limb or the body is cold Or there may be dull aching pains intermittent neuralgic pains which may be severe or a sensation of coldness or numbness which may be intense Painful cramp in the muscles which are about to be affected is comparatively common The attention of the patient may be first drawn to his malady by the altered appearance produced by the atrophy, and this is more common when the commencement is in the hands where the subcutaneous tissue is thin and the region constantly in view More often the disability consequent upon the weakness is noticed first, this is always the case where the commencement is in the bulbar muscles and usually also where the muscles of the legs proximal muscles of the arms and trunk muscles are first involved Lastly the fibrillation may be so marked as first to attract notice

The *muscular wasting* which constitutes the most characteristic feature of the disease may commence in any group of the skeletal muscles whatsoever It may be first manifest in such rare situations as the facial muscles intercostal muscles muscles of the back and abdominal muscles The commonest situation is in the muscles of the upper limb where the distal (intrinsic muscles of the hand) or the proximal muscles (deltoids spinati etc) are first affected in about an equal number of cases In the hand the muscles of the thenar eminence are the first to waste and this is followed by atrophy of the hypothenars of the lumbricals and of the interossei with the usual flattening of the palm exposure of the flexor tendons in the palm from loss of the bulk of the lumbricals hollowing of the interosseal spaces and a tendency to the claw attitude of the hand This *main en griffe* is never so marked in this disease as in paralysis of the ulnar nerve syringomyelia etc because the wasting soon affects the long flexors of the fingers and moreover contractures of the affected muscles are not marked in progressive muscular atrophy When the upper arm is primarily affected the wasting is usually first seen in the deltoids whence it spreads upwards involving the spinati and the muscles attaching arm to scapula and arm and scapula to trunk Among these muscles some tend to escape the atrophy relatively or to be affected much later than others and these are the triceps the latissimus dorsi the lower half of the pectoralis major the levator anguli scapulæ and especially the upper half of the trapezius which for this reason was called ultimum moriens by Duchenne In the limbs the wasting always commences in one limb but soon spreads to the corresponding limb of the opposite side and tends ultimately to become symmetrical

The type of muscular wasting which is characteristic of amyotrophic lateral sclerosis and present less often in other forms of progressive muscular atrophy is that which was called by Gowers *tonic atrophy* It might be expected that when degeneration began in a group of anterior horn cells the corresponding muscles would gradually lose their tendon reflexes and become inexcitable But in amyotrophic lateral sclerosis while the muscles waste their tendon jerks become and remain exaggerated and the wasting muscles though they hang flabbily on the limbs become hyperexcitable to percussion and they show spontaneous contractions of groups of fibres known as fibrillary twitchings or *fibrillation* or fasciculation (see p 1559)

In other forms of progressive muscular atrophy the wasting muscles are more liable to lose their tendon jerks they may be inexcitable to percussion of the muscle bellies and they show less if any fibrillation

Accompanying the muscular wasting there is usually considerable wasting of the subcutaneous tissues and the skin becomes very loose and the reduced and separated muscles stand out when they are voluntarily contracted In some cases the subcutaneous tissue does not waste and may even be increased (especially in the lower limbs) and then the muscular wasting may be masked for a long time even till paralysis becomes complete There may be an appearance of vasomotor paralysis—redness blueness and some swelling of the periphery—but this seems to occur much more as the result of the continual pendent position of the hands and of the absence of muscular activity which normally aids the circulation than as the result of any definite vasomotor palsy

While in the most usual type of case muscular wasting is going on in the upper limbs slight signs of spasticity gradually develop in the lower limbs The knee jerks and ankle jerks become exaggerated and after a time the plantar reflexes become extensor There is not often a severe degree of spasticity and sometimes palpable spasticity is absent although the reflex signs of pyramidal disease are present The parts which become spastic do not in general develop any wasting

Spasticity from the upper motor neurone disease may develop in the lower extremities before there are any signs elsewhere of atrophic paralysis due to the lower motor neurone lesion and such cases present the physical signs of a primary lateral sclerosis It must therefore be borne in mind that a case presenting such features in an adult may eventually prove to be one of amyotrophic lateral sclerosis

In some cases of progressive muscular atrophy no abnormal clinical signs are found in the lower limbs but post mortem degeneration of the pyramidal tracts is evident

Next in order of frequency to initial wasting in the upper extremities comes the incidence of the disease upon the muscles concerned in facial expression articulation mastication and deglutition and in lesser degree upon the muscles of phonation The disease may be confined to these muscles throughout the whole of its course From the widely different clinical picture resulting and from the fact that all these muscles are supplied from the brain stem and upper two segments of the spinal cord this form of the disease has borne the name of *progressive bulbar paralysis* or *labio glosso pharyngeal paralysis* The wasting commences in the intrinsic muscles of the tongue and spreads thence to the orbicularis oris to the extrinsic muscles of the tongue pharynx and larynx to the muscles of mastication and eventually but in less degree to the facial muscles generally but only in rare cases are the oculomotor muscles affected

The intrinsic muscles of the palate the constrictors of the pharynx the intrinsic muscles of the larynx and the muscle of the œsophagus are little affected This seems at first an anomalous and astonishing fact, considering how great and important are the troubles with deglutition in bulbar paralysis But the anomaly disappears at once when one considers that the muscles which are concerned with buccal deglutition are

the muscles of the tongue, those forming the floor of the mouth including the mylo hyoid and the digastric, the muscles which raise and lower the jaw and those of the lips Further, the muscles which are most important in pharyngeal deglutition are those which raise and lower the hyoid bone and larynx as a whole, and these are the stylohyoid and stylopharyngeus, the palatoglossus and palatopharyngeus the genio hyoid, thyrohyoid sternohyoid, sternothyroid and omohyoid All these muscles are early and severely affected in bulbar paralysis, and when they fail, the intrinsic muscles of the palate are unable to shut off the naso pharynx, the constrictors of the pharynx are entirely unable to perform the act of deglutition and the intrinsic muscles of the larynx—though phonation is never lost—are unable since the larynx is unfixed by the extrinsic muscles, to modulate the tone of the voice The very active pharyngeal reflex and the difficulty in using the laryngoscope on account of spasm of the pharynx in the subjects of this disease are very good clinical evidence that the pharyngeal constrictors are not affected

The earliest physical sign of bulbar paralysis is the loss of the finer movements which are essential for correct articulation and consequently a slurring dysarthria develops and increases and the consonants become less and less distinct until they are inaudible The failure of the palate to close upon the posterior pharyngeal wall begets a nasal element in the voice Later the patient becomes unable to interrupt his blast at any of the stop positions and his utterance becomes a long moaning monotonous inarticulate sound His phonation remains, but he cannot alter its pitch nor divide it into parts of speech except by taking a fresh breath The orbicularis oris is early affected and the lips lose their firmness and become thin, and as they weaken the unopposed retractors of the angles produce a wide straight mouth both at rest and in emotional action Whistling and pursing up the lips become impossible and ultimately there is much dribbling of saliva for this can neither be retained by the lips nor swallowed The tongue shows fine fibrillation, and as it wastes it loses its point becomes rounded and is protruded with difficulty Its surface becomes dimpled and faceted in the end it consists solely of the covering mucous membrane the glands and the fibrous tissue and lies motionless in the floor of the mouth re sembling a crinkled mushroom The muscles of mastication all become affected The bite becomes feeble and the mouth cannot be opened against resistance In the late stages the jaw drops and the mouth is constantly open The combined weak ness of tongue and buccinators makes it very difficult for the patient to keep his food between his teeth in mastication and often he aids his disability by digital pressure upon the cheeks Nasal regurgitation is not uncommon The difficulty in swallow ing is greatest with fluids for these require quick action, and is next greatest with lumpy solids for these necessitate powerful action It is least with food of a porridge like consistency, and this should be carefully borne in mind in feeding the patients

The other muscles of the face are affected later and to a much less severe degree than is the orbicularis oris It is as if there were a physiological selection on the part of the disease for the nervous mechanism subserving mastication and deglutition Still in the majority of cases there is bilateral general facial weakness and wasting which with the peculiar mouth and dropping jaw produce a characteristic facies which can be instantly recognised If the upper facial muscles are tested by raising the eyelid with the finger against resistance invariably they will be found to be weak Only in very rare cases does the atrophy extend to the oculo motor muscles As in the paralysis of the limbs so also in bulbar paralysis concomitant signs of both upper motor neurone and of lower motor neurone lesion may exist When such tonic atrophy of the bulbar muscles is present the symptomatology and clinical appear ance are the same as have been above described for the simple atrophic form with the exception that the jaw jerk and the other muscle jerks of the bulbar region which are absent in the latter condition are brisk in the tonic atrophic form And

further it must be remembered that the additional element of spastic paralysis adds greatly to the degree of the paralysis as a whole

In less common cases of progressive bulbar paralysis the upper motor neurone lesion alone is in evidence and the bulbar paralysis is purely spastic Here the symptomatology as regards articulation deglutition etc is the same and the facial aspect identical with that of the simple atrophic and tonic atrophic forms The muscle jerks are brisk The appearance of the tongue however is quite different it is smooth narrow stiff and drawn into a narrow compass by the spasm of the muscles composing it It appears too small for so large a mouth There is no fibrillation and the muscles are nowhere wasted

The muscles of the back of the neck the splenius complexus etc., are not uncommonly the first muscles to be affected with the wasting of progressive muscular atrophy There is increasing difficulty in extending the head which drops forward causing a characteristic attitude which is associated with a constant overaction of the frontales which raise the brows to clear the line of vision when the head is dropped forward so giving rise to a permanently furrowed brow The loss of substance in the muscles of the back of the neck together with the dropping forward of the head causes the lower cervical and upper dorsal spines to stand out in undue prominence and to give an appearance approximating to that of an angular curvature

Primary affection of the lower extremities is much less common than that of the upper extremities bulbar region or neck muscles The anterior tibial and peroneal muscles are usually attacked first and less commonly the quadriceps The clinical type is that of flaccid atrophy in most of the cases Tonic atrophy which is so common in the upper limbs and in the bulbar region is rare in the legs

Wherever the site of commencement of progressive muscular atrophy may be it invariably spreads to other regions sometimes slowly and with periods of arrest which may last for years sometimes with remarkable rapidity The manner of spread is usually in terms of the contiguity of the affected elements in the nervous system but it is sometimes in terms of the physiological association of the muscles as is commonly seen in the bulbar forms of the malady When the disease is definitely installed the appearance of fibrillation in any muscles otherwise unaffected is a sure sign that atrophy will shortly commence in those muscles

According to the method of advance shown by the disease cases of progressive muscular atrophy fall into two groups which it is important to distinguish In the first group the atrophy spreads locally and slowly and remains confined to one region of the body during most of the course of the malady These cases are always of the simple atrophic type and they usually survive a long time Such cases however tend to become general just before the end In contrast with the local type of the affection is the group in which the manifestations commencing locally spread within a comparatively short time to many parts of the body or even become universal The spread may be very rapid and the end may occur in a few months or it may be slower but it is unusual for any of the cases forming this group to survive for more than 2 years This group comprises (1) the generalised cases of simple flaccid atrophy (2) all the cases of amyotrophic lateral sclerosis and (3) most of the bulbar cases

Fibrillation is a most important symptom of the disease and is an associate of the muscular atrophy It precedes the wasting of the fibres and is a sure herald of the advent of wasting in this disease It ceases to occur when the muscle is completely wasted and is not seen when the atrophy is not progressing On account of the importance of fibrillation as a diagnostic sign of progressive muscular atrophy it is important here to consider those other conditions in which it is met with clinically It occurs in syringomyelia and in peroneal atrophy but only when the muscular atrophy is progressing and therefore it is only an occasional symptom in either disease It is often very marked in cases of interstitial neuritis (sciatica etc) It

occurs in a most magnified and conspicuous form in certain conditions of gastro enteritis and is presumably due to an intoxication and to this form of fibrillation the term myokimia has been applied It is not met with in polyneuritis polio-myelitis, myopathy nor in the common gross lesions of nerve trunks nerve roots or spinal cord

The *electrical reactions* of the affected muscles vary according to the degree of degeneration Since normal and degenerate fibres are stimulated side by side in the affected muscle there will be *some lowering of the response to faradism with a* tendency to a polar change This is known as the ' mixed reaction and it is common to all diseases in which muscle degenerates fibre by fibre Faradic excitability lessens as more of the muscle fibres degenerate and when degeneration is complete all electrical excitability is lost In tonic atrophy the excitability of the affected muscles to direct mechanical stimuli such as percussion is increased so long as any living muscle remains

Contractures are conspicuous by their absence in this disease which is thus strongly contrasted with peroneal atrophy and some other muscular atrophies If the atrophy becomes complete in a whole limb the end result is that the limb is flail like and without contracture

Mental alterations are constantly present in the cases in which the bulbar region is affected Emotional instability and hyperexcitability are the usual change The patient is easily excited to tears or to laughter by trivial causes and when so excited cannot control his expression of emotion He himself feels little joy or grief during the paroxysms of laughing or crying

Sphincters —In the majority of the cases these are not affected but every now and then dysuria in any of its forms occurs and it may occur early in the course of the malady and it may be severe Loss of sexual power is very common

Reflexes —The reflexes are modified in this disease *on the one* hand by spasticity when this is present and on the other by the muscular atrophy which may prevent response in the affected muscles The pharyngeal reflex in bulbar cases is usually brisk, notwithstanding the statement to the contrary, which most writers upon this *subject have recorded but the response is not the normal response involving* all the muscles concerned in deglutition for these are atrophied and paralysed it is confined to the constrictors of the pharynx and the muscles of the palate with the feeble co operation of such of the somatic bulbar muscles as are still able to act *The plantar reflexes are usually of the extensor type when the legs are spastic* but this does not always obtain Similarly the abdominal reflexes do not disappear so constantly or so early as is the case in disseminated sclerosis for example and they may persist when the legs are markedly spastic and extensor plantar responses have appeared In cases of tonic atrophy the *tendon reflexes are everywhere increased* even in regions where the atrophy is severe and in this type of the malady they never disappear The same increase of the muscle jerks occurs in the purely spastic cases In simple atrophic cases the tendon jerks disappear *pari passu* with the wasting of the muscles

Cerebrospinal fluid —The cerebrospinal fluid is always quite normal by all the tests at present in vogue It does not usually contain more than one cell per c mm , and no change has been detected in its chemical constitution

Diagnosis —*The malady has to be distinguished from the many conditions* in which progressive weakness and wasting of the muscles occur from those in which muscular wasting and spasticity are conspicuous clinical features and lastly from other diseases in which bulbar symptoms are early evidenced Injury of the cervical enlargement of the spinal cord *gives rise to a limited degree of* wasting in the upper limbs and spasticity of greater or less intensity in *the lower limbs* (see p 1541) The wasting in the upper limbs becomes apparent some weeks after the injury and affects the muscles corresponding to the injured segments of the cord which are

commonly those of the forearms and hands But weakness of these muscles and the spastic weakness of the legs are maximal immediately after the injury, and power usually shows an improvement during the succeeding weeks or months whereas in progressive muscular atrophy the weakness wasting and spasticity come on insidiously and progress steadily It must be realised that although bony injury is commonly present injury of the cervical cord may occur without any fracture or dislocation of the cervical spine Furthermore a moderate degree of weakness of the limbs may escape observation while the patient is in bed after an accident, or they may be ascribed to other causes and so the signs resembling amyotrophic lateral sclerosis may not be discovered until several weeks after the occurrence of the lesion responsible for them Inversion of the supinator jerk (see p 1541) is a common sign in cases of injury of the cervical enlargement but rarely if ever occurs in progressive muscular atrophy Syphilitic amyotrophy (p 1470) may be indistinguishable from progressive muscular atrophy except by the results of the Wassermann reactions in the cerebro spinal fluid and blood Peroneal muscular atrophy very closely resembles progressive muscular atrophy in that slow wasting and fibrillation of the muscles are the chief clinical features The points which distinguish the two conditions are that peroneal atrophy is often a familial disease and is apt to commence in childhood when it is unusual for progressive muscular atrophy to begin The location of the atrophy is peculiar and when well marked in the periphery of all four limbs as is common in this disease cannot be confused with progressive muscular atrophy since the latter disease never has this distribution Syringomyelia is easily distinguishable by the early and striking loss of pain and temperature sensibility Cervical rib not uncom monly produces atrophy of the intrinsic muscles of the hand and though this is usually confined to one hand it may be bilateral Further it is exceptional for the atrophy to involve all the small hand muscles simultaneously or equally It picks out the opponens pollicis first and most severely and is not uniform for all the hand muscles as in progressive muscular atrophy Pain in the distribution of the eighth cervical and first dorsal roots and some loss of sensibility may be present. The atrophy remains local and is never accompanied by fibrillation The abnormal rib is easily discoverable on radiographic examination It must be borne in mind that cervical ribs are not uncommon and that their presence does not necessarily prove the cause of atrophy of the hand muscles for cervical ribs may be present in the subjects of progressive muscular atrophy syringomyelia or any other disease

The diagnosis of progressive muscular atrophy from the primary muscular dys trophies seldom causes serious difficulty The latter occur in general at a much earlier age and several members of a family may be affected the incidence of the wasting is almost invariably on the proximal muscles the weakness is out of pro portion to the apparent wasting fibrillation is absent and the progress of the disease is very much slower than that of progressive muscular atrophy Dystrophia myo tonica is at once separated from progressive muscular atrophy by the myotonus when this latter symptom is present When myotonus is absent, the characteristic wasting of the sternomastoids and of the muscles of the thighs the age of the subject and sometimes the presence of cataract should suggest the diagnosis Arthritic muscular atrophy occurs in the regions of joints which show easily recognisable disease Fibrillation does not occur nor are there alterations in the electrical excita bility of the wasted muscles

Lesions of peripheral nerve trunks may be diagnosed by the history of a local cause by the discovery of a palpable local lesion upon the course of the nerve and by the confinement of the atrophy to the distribution of one particular nerve while pain and sensory loss often occur in that same distribution

Lesions of the nerve roots and especially those produced by pachymeningitis and by neoplasm in the vertebræ may cause signs and symptoms so closely resembling those of the more rapid forms of progre sive muscular atrophy as to render correct

diagnosis very difficult Such a lesion in the cervical region for example may give rise to wasting of the hand and forearm muscles and a spastic condition of the legs resembling exactly a condition of amyotrophic lateral sclerosis, without deformity or rigidity of the spine and without pain or sensory loss In such cases of difficulty the course of a little time will bring the advent of the conclusive symptoms of a local pressure lesion It is important in this connection to remember that pressure upon the spinal cord results in hyperalbuminosis of the cerebrospinal fluid and if the lesion causing the pressure is syphilitic there is likely also to be lymphocytosis in that fluid neither of which conditions is found in progressive muscular atrophy

Diagnosis is most difficult in those cases where spasticity in the limbs is the first sign of progressive muscular atrophy and where such spasticity precedes the appearance of any muscular atrophy by a long time If it be clearly borne in mind that spastic paralysis may be the earliest and for a time the only sign of progressive muscular atrophy, and that among the many diseases of the nervous system which commence with the same clinical picture of spastic paralysis a certain diagnosis cannot be made until further distinguishing signs appear error will be avoided The importance of the examination of the cerebrospinal fluid in doubtful cases cannot be too strongly emphasised

Course and Prognosis —The nature of the disease is to progress and to extend its area of invasion until a fatal issue is reached The progress may be rapid and the end may be reached in a few months or it may be slow and several years may elapse before death occurs The local types of progressive muscular atrophy of slow onset are the most gradual in their development and these are often characterised by periods of arrest in the progress of the disease The generalised simple atrophic type of the disease is the most rapid especially when it commences with severe initial flaccid paralysis without atrophy

In the bulbar types of the disease, and in the common type of amyotrophic lateral sclerosis, the course is for the most, steadily progressive Every type will show how ever upon occasion exacerbations and remissions and the exacerbations are the most important and in the bulbar types may bring about the end in a few hours Of particular interest are rapid extensions of a flaccid paralysis which may occur in a few hours and which resemble and indeed are identical with onset of the disease with initial flaccid paralysis without atrophy, which has been already described Whatever type of the disease be present it tends in the end to spread and to become general

Involvement of the respiratory muscles or severe bulbar symptoms and the pulmonary complications which may accompany either condition, may bring about the fatal issue It is usual however for death to occur in a manner which is common to so many degenerative nervous diseases a rapid increase of the paralysis is associated with an increasing lethargy, which soon deepens into a rapidly fatal coma *It is* uncommon for death to occur from intercurrent maladies The average tenure of existence after definite signs are present is under 1 year in the generalised *flaccid* type and it may be as short as 2 months Bulbar symptoms are not generally survived for more than 12 months Localised cases of simple atrophy may *live for many* years Some of the patients in whom a positive Wassermann reaction is found improve and the disease is sometimes arrested by *antisyphilitic treatment*

The progressive character of the disease renders the prognosis grave in every case There are some cases occurring *in middle life which resemble* cases of progressive muscular atrophy of local distribution and slow course, which become finally arrested or even recover *the true nature of such cases* is doubtful but it is probable that they are allied to polyneuritis

In amyotrophic lateral sclerosis the average duration of life is seldom more than 3 years from the onset When bulbar symptoms are present the average duration is under 2 years In the generalised cases the average duration is under 1 year Widely

spread fibrillation in muscles which are neither weak nor wasted, is the constant herald of generalisation and renders the immediate prognosis serious In cases where syphilis is present the prognosis is more favourable and there is even a possibility of arrest and improvement if energetic treatment of the associated condition is provided Rapid extension of the weakness the advent of bulbar symptoms involvement of all the respiratory muscles and especially general asthenia and drowsiness are the signs which usher in the fatal result

Treatment —This malady seems to be entirely uninfluenced by any treatment that has hitherto been adopted At one time dramatic claims were made in respect of vitamin E (tocopherol acetate) given in doses of 3 mg thrice daily This was said to arrest wasting and weakness and in early cases to effect rapid improvement These claims however have proved illusory It remains therefore to secure favourable conditions of life for the patient and to maintain the general health in as perfect a state as possible Massage and passive movements are useful as giving bodily comfort to the patient and satisfying him that something is being done for him In bulbar cases the dysphagia must be aided by avoiding liquids and solids, and by serving all the articles of diet in pultaceous form Salivation which is so troublesome in this condition may be greatly helped by the administration of hyoscine or belladonna by the mouth

PERONEAL MUSCULAR ATROPHY

Synonyms —Charcot Marie-Tooth Type of Muscular Atrophy, Neuritic Type of Muscular Atrophy

Definition —This is an absolutely distinct and peculiar form of muscular atrophy, with a frequent tendency to occur in several members of the same family It usually commences in mid childhood and after progressing for some 20 years or less comes to a final arrest The atrophy always commences in the intrinsic muscles of the feet, and is throughout strictly distal in distribution The muscles of the face and trunk and the proximal muscles of the limbs are never affected The atrophy leaves a peculiar elastic fibrosis in the affected muscles so that the incapacity caused by this disease is much less than in any other form of muscular atrophy of like degree Sensibility is often slightly affected and there may be deep sensory loss The essential morbid anatomy is a primary neurone atrophy of the anterior horn cells and of some of the afferent neurones in Clarke s column

Ætiology —The disease usually commences between the fifth and tenth years of childhood but it may appear as late as the fourth decade of life Males and females are both affected Heredity plays an important part in the incidence although isolated sporadic cases are not uncommon It may exhibit every type of inheritance The malady often occurs in families and has been traced through five generations it may skip a generation and then reappear

Pathology —The anterior horn cells of the affected regions show a slowly progressive atrophy and disappearance with corresponding atrophy of fibres in the peripheral nerves The cells of Clarke s column show signs of degeneration as do also some of the fibres of the posterior columns of the spinal cord and especially those of the postero lateral column Slight degeneration in some of the fibres of the pyramidal tracts is usually found The affected muscles show a simple atrophy of the muscle fibres indistinguishable from that seen when a motor nerve is divided There is a simple shrinking of the fibres which stain progressively and more and more deeply with hæmatoxylin lose their striation and finally disappear Secondary fibrotic changes accompany the atrophy together with sclerosis of the arteries of the muscle

Symptoms —Muscular atrophy dominates the clinical picture of this malady

It is strictly distal in distribution and this feature will serve to distinguish peroneal atrophy from any other form of muscular atrophy This is to say it does not affect one particular muscle but the distal ends of all the muscles below a certain level on the limb leaving the proximal ends of the muscles normal and it advances up the limb inch by inch, the separation of the wasted portion of the muscle from the normal portion being always transverse to its length In other words, the muscle fibres seem to waste in terms of the length of the spinal axons which supply them The wasting commences always in the intrinsic muscles of the feet and hollowness of the instep and thinness of the feet together with retraction of the toes and the difficulty which the pes cavus so produced entails in fitting boots first draw attention to the disease As the process advances the lower segments of the anterior tibial peroneal and calf muscles become affected, and the limb is subsequently involved until the lower third of the thigh is reached, at which stage the disease is invariably arrested This slow spread of the atrophy from the distal towards the proximal portion of the limb, gives rise to a unique and characteristic feature in the appearance of the legs at the several stages of the disease As an example the complete atrophy of all the muscles below the middle and a well developed musculature in the upper half of the leg, give rise to the inverted fat bottle calf When the atrophy has involved the lower third of the thigh the lower end of the femur bare of muscle and covered only by skin and tendons contrasts strongly with the well developed muscles of the upper thigh and causes the thigh to resemble an inverted champagne bottle

Some years after the atrophy has become marked in the lower extremities and in the usual run of cases just before the age of puberty, the intrinsic muscles of the hands and first those of the thenar and hypothenar groups begin to waste and this wasting may extend as high as the middle of the forearm It must be borne in mind that the disease may become arrested at any period of its spread and especially that the upper extremities often escape altogether With the exception of the lower part of the thighs the proximal segments of the limbs do not become involved and the muscles of the head neck and trunk remain unaffected

The affected regions of the muscles waste absolutely, and leave a very elastic fibrous tissue The electrical excitability in the wasted regions becomes first lowered and then lost and in the earlier stages may show a mixed reaction in which there is lowering of excitability to faradism with a tendency to an inverted polar reaction Fibrillation of the muscles is an important sign It is seen only when the disease is progressing and in the muscles which are obviously wasting It is never general as in some cases of progressive muscular atrophy and since peroneal atrophy is at times advancing and at other times stationary, fibrillation may be in one case conspicuous and in another never seen It disappears entirely when the progress of the malady becomes finally arrested and is therefore useful as a clinical indication of active advance of the disease Contractures always occur and from the nature of the distribution of the atrophy are necessarily confined to the feet and the hands In the feet pes cavus with retracted toes is the rule but sometimes and in some stages of the disease the feet and toes may be dropped and the feet inverted The sphincters are unaffected The ankle jerks are diminished or lost in proportion to the wasting of the calf muscles In the final arrested stage they are usually lost The knee jerk is always retained and is usually brisk The plantar reflexes are usually lost early so far as any response in the foot is concerned but some response in the upper thigh muscles upon stimulating the plantar region often remains Pain tenderness and cramp are entirely absent. Conspicuous loss of sensibility is uncommon but slight loss of deep sensibility loss of the vibration sense and relative tactile loss may often be detected upon careful examination but in rarer cases all forms of sensibility may be severely affected or even entirely lost. Perforating ulcers may be met with upon the soles of the feet and are explained by the thinness of the feet and their deformity which coupled with the clumsiness of the use of the feet lead to the formation of

severe corns which break down into perforating ulcers Loss of sensibility also is a factor in their production

The most striking of all the clinical features of peroneal atrophy is the comparatively slight disability caused by the wasting of the muscles and consequent paralysis, and even the sensory loss when it is present

Course —The course is irregularly progressive for a number of years only and the advance of the disease ceases usually in the third decade of life Exacerbations of the weakness are likely to be followed in every case by considerable improvement, owing to the secondary fibrosis in the muscles

Diagnosis —Peroneal atrophy in the early stages is easily confused with progressive muscular atrophy in that wasting of muscles and fibrillation are the conspicuous features The onset usually in childhood and the fact that the feet are affected first the peculiar distal distribution and the presence of any familial incidence are important But the only distinction which is absolute is the distribution for progressive muscular atrophy may begin in childhood and peroneal atrophy may not appear till after middle life and often familial history is absent in the latter malady In the course of time the diagnosis always becomes clear for progressive muscular atrophy never keeps to the classic distribution of peroneal atrophy nor is it followed by the peculiar fibrosis which characterises the latter

Dystrophia myotonica when commencing in the peroneal muscles may for a time closely simulate peroneal atrophy The presence of the least sign of myotonia the involvement of the face and the atrophy of the sternomastoids will establish the diagnosis

The usual forms of myopathy are at once separated from peroneal atrophy by the distribution of the muscular weakness and wasting which in the former group of maladies is conspicuously upon the face trunk and proximal muscles of the limbs and in the latter upon the distal muscles Peripheral neuritis is more rapid in its onset and is apt to be associated with marked sensory disturbances both objective and subjective and the paralysis is in terms of individual muscles which is not the case in peroneal atrophy

Treatment —The general health should be carefully maintained and the nutrition of the affected muscles aided by the application of massage Care must be taken on the one hand to avoid over fatigue of the affected muscles and on the other to ensure such regular exercise as is compatible with their capacity Bicycling for example since it employs chiefly the thigh muscles is a better form of exercise for these patients than is walking In no circumstances should tenotomies be performed for the deformity of the feet for such measures tend to destroy the effect of the conservative fibrosis so essential to the production of a useful limb The use of heavy mechanical supports is to be avoided above all things Light well fitting boots so as to interfere as little as possible with the exercise of the damaged muscles are essential

PROGRESSIVE SPINAL MUSCULAR ATROPHY OF CHILDREN

Synonym —The Werdnig Hoffmann Disease

Definition —This is a malady of the first year of infancy often incident upon several children of the same parents and characterised by the gradual development of progressive muscular weakness and atrophy which affects the proximal muscles first and most increases to a complete paralysis of trunk and limbs and finally affects the bulbar muscles The disease is invariably fatal in from a few weeks to several months The most striking pathological changes are a progressive degeneration and disappearance of the ventral horn cells of the spinal cord and of their analogues in the brain stem

Ætiology —In some of the cases the paralysis is noticeable at the time of birth and the disease is obviously of pre natal development In others the children are quite healthy at birth, and the disease develops some time during the first year of life and most frequently within 8 weeks of birth Though sporadic cases may be met with, yet in the majority of instances several children of the same mother are affected Both the pre natal cases and the post natal cases may be met with among the children of the same mother The sexes seem to be equally affected No maternal ill health during pregnancy has been noticed, and nothing is known about any other ætiological factor

Pathology —The most extensive changes are found in the ventral horn cells throughout the spinal cord and brain stem and at many levels no normal cells what ever are to be seen Tigrolysis, swelling and glassiness of the cells extrusion of the nuclei disappearance of the dendrites shrinking of the cells and final disappearance is the sequence of the changes Degeneration of the anterior roots and of the peri pheral motor nerve fibres consequently occurs These changes are not confined to the lower motor neurones, for in some cases examination by the Marchi method shows extensive degeneration throughout the posterior columns of the cord indicating that lower sensory neurones were also considerably affected

The muscles show intense degeneration with hypertrophy of some fibres and atrophy of most of the fibres waving moniliform shape hypernucleation of the spindles, general nuclear increase and fibrosis

Symptoms —In the cases which are pre natal the malady is noticed at the time of birth on account of the tonelessness flaccidity and the poorness of movement in the trunk and proximal muscles of the limbs In the post natal cases there is a gradual onset of similar weakness and flaccidity in the trunk first and in the limbs afterwards which usually commences within 6 weeks of birth but which may not appear until towards the end of the first year of life The weakness seems always to be least marked in the periphery of the limbs where curious slow involuntary movements of the fingers and toes have been noted in many of the cases The paralysis is followed by a rapid and extensive wasting of the muscles, accompanied by occasional fibrillary twitchings Since these children are not only well nourished but often put on much fat during the illness wasting of the muscles may not be apparent on inspection or palpation It can however immediately be detected by radiography which distin guishes sharply between fat and muscle

As the malady progresses the trunk muscles become completely paralysed the intercostal muscles being always paralysed before the diaphragm The limbs become progressively weaker and lastly bulbar paralysis supervenes in those cases where death has not already occurred from respiratory paralysis The reaction of degenera tion is present in the affected muscles Sensibility may be unimpaired but in several of Collier s cases there was conspicuous loss of pain sensibility over the limbs and trunk The sphincters are unimpaired until the very last stages of the disease The superficial and deep reflexes are lost The ocular muscles are not affected and intelligence is preserved throughout

Diagnosis —The peculiar and striking features of the disease make the diagnosis easy if the symptomatology be known Amyotonia congenita presents the same helplessness and flaccidity of trunk and limbs as does the Werdnig Hoffmann disease and further resembles it in being sometimes congenital and sometimes having an onset very early in life In amyotonia congenita however the paralysis is not com plete, and it tends to improvement and not to progressive increase Contractures also occur which are not found in the Werdnig Hoffmann disease and, lastly the definite spinal cord changes of the latter malady are not found in the former Green field however considers that amyotonia congenita and Werdnig Hoffmann paralysis are different aspects of a single disease

Course and Prognosis —The course is invariably progressive and is more rapid

the earlier in life the disease commences and it is most rapid of all in the pre natal cases which are usually fatal within a few weeks With an onset some weeks after birth life is usually continued for several months and a few cases have been reported with an onset towards the end of the first year in which death has been delayed until the third or fourth year

Treatment —No treatment is known to influence the course of the malady

DISORDERS OF THE PERIPHERAL NERVES

LOCAL LESIONS OF NERVE ROOTS AND NERVE TRUNKS

Individual peripheral nerves may be damaged by a large number of agencies Trauma may affect them in a variety of ways Direct penetration by a sharp body such as a knife or glass or the passage of a fragment of a projectile may sever the nerve completely or partially Injury by a blow with a blunt agent or severe commotion in surrounding tissues such as occurs with the passage of a projectile near the nerve may destroy the axons without interrupting the continuity of the more resistant medullary sheaths and perineurium Recovery of such a nerve requires the growth of new axons down the surviving medullary sheaths Similar injuries of less intensity may temporarily abrogate the function of the nerve but be followed by recovery of function in a matter of hours or days For these three degrees of nerve injury Seddon has suggested the names neurotmesis axontmesis and neurapraxia respectively Nerves may also be injured by trauma of a less violent but more sustained character as is seen in the common varieties of pressure palsy such as Saturday night paralysis crutch palsy palsies from pressure of plaster and other splints and chronic over stretching as in the case of the ulnar nerve Peripheral nerve lesions may follow a variety of general infections such as pneumonia dysentery and streptococcal illnesses Nerves may be involved in specific inflammatory processes such as leprosy Finally they may be involved in new growths The most important example of this is in filtration with carcinoma from a neighbouring focus but nerves may be the site of isolated neurofibromata or multiple lesions in cases of Von Recklinghausen s neuro fibromatosis

PHRENIC NERVE

This nerve supplies the diaphragm Paralysis results most often from disease of the spinal cord but the roots may be implicated in disease of the spine and the trunk may be injured in its course through the neck and thorax by wounds or tumours Bilateral paralysis occurs in lesions of the cord and spine and in polyneuritis espec ially of the diphtheritic and acute infective varieties Other causes usually affect one side only When the diaphragm is completely paralysed the normal inspiratory protrusion of the upper part of the abdomen disappears or is replaced by retraction of this part with each inspiration During rest so long as the lungs are healthy the respiratory rate does not increase but if bronchitis or pneumonia arises as a com plication or if the patient exerts himself the diminished reserve of respiratory power is seriously felt When one nerve only is affected the diaphragm does not move on that side but becomes permanently elevated as a result of collapse of the base of the corresponding lung This is rarely detected by observation of the abdominal move ments but is easily seen on the radiograph screen It produces no discomfort

THE LONG THORACIC NERVE

This nerve supplies the serratus anterior muscle When all the fibres of this muscle contract the scapula moves upwards forwards and outwards It contracts

with the pectoralis major in the action of pushing forward the point of the shoulder and in the rapier thrust movement It also assists the deltoid in raising the arm When it is paralysed alone, the position of the scapula at rest is unaltered but if the trapezius and the rhomboids are paralysed as well the scapula drops and its lower angle is displaced inwards Paralysis of the serratus anterior is best demonstrated by causing the patient to hold the arms outstretched before him The arm is not raised so high on the affected as on the normal side, because the scapula is not fixed and the deltoid works at a disadvantage Viewed from behind the deformity is characteristic The vertebral border of the scapula stands out prominently and the hand can be pushed between this bone and the thorax— winged scapula On raising the arm from the side there is difficulty in attaining the horizontal position, but the winging of the scapula is less apparent

The nerve may be damaged by carrying heavy weights on the shoulder by falls or blows on the shoulder, and by continued muscular effort with the raised arm The nerve may be injured alone in gunshot wounds but as a rule it is associated with lesions of the brachial plexus In addition a serratus anterior palsy may develop suddenly in an otherwise healthy person after exposure to cold or as part of a rare reaction to the administration of serum or antitoxin In such neuritic cases and in the cases caused by compression severe neuralgic pains in the neck precede the onset of paralysis Recovery is always very slow and the defect may be permanent

BRACHIAL PLEXUS

The brachial plexus may be injured by stabs in the neck by penetrating missiles by dislocation of the shoulder or fracture of the clavicle or by pressure of a tumour aneurysm or cervical rib Further the nerves may be torn by forcible dragging on the arm in accidents or during delivery In most cases the lesion is partial and the symptoms conform in the main to one of the following types

Upper plexus paralysis (Erb s palsy) —This results from an injury to the fifth and sixth cervical roots The muscles paralysed are biceps deltoid brachialis brachioradialis (supinator longus) supraspinatus infraspinatus rhomboideus subscapularis clavicular portion of pectoralis major serratus anterior latissimus dorsi teres major The arm cannot be flexed at the elbow (flexors of forearm) nor raised and abducted (deltoid) The movements of the wrist and fingers are not impaired Adduction of the arm is weak (pectoralis major) and rotation is feeble or absent (spinati) On attempting to oppose the shoulders, the scapula on the affected side passes farther from the middle line (rhomboideus) The hand of the affected side cannot be placed on the buttock of the sound side (latissimus dorsi)

The reaction of degeneration is often complete in the deltoid and flexors of the forearm and nearly so in the spinati It is usually incomplete in the other muscles Sensation is diminished or lost along the outer border of the whole limb immediately after the injury but improvement sets in rapidly For some time the patient experiences pins and needles and burning sensations in the affected area which last longest in the thumb and index finger The biceps reflex is lost

Lower plexus paralysis (Klumpke s palsy) —This results from a lesion of the eighth cervical and first dorsal roots or of the common trunk of the median and ulnar nerves The intrinsic muscles of the hand and the flexors of the wrist and fingers are paralysed and the inner border of the forearm and hand is anæsthetic When the roots are damaged sympathetic fibres may be implicated with the production of myosis narrowing of the palpebral aperture enophthalmos and alterations in sweating on the face neck arm and upper part of the chest on the affected side

Middle plexus paralysis —This form of paralysis is a common result of gunshot injuries of the plexus It affects the muscles supplied by the radial and axillary nerves —posterior cord As the nerve to the latissimus dorsi arises from the same cord

this muscle is often paralysed as well In addition to these simple types more complicated paralyses occur in which various parts of the plexus are injured together

Paralysis of the medial cord of the plexus —Atrophy is confined to the intrinsic hand muscles and the sensory loss is confined to the hand

Incomplete lesions of the brachial plexus show a remarkable tendency to spontaneous recovery In many cases recovery is complete in 6 months to 2 years, in others it is partial and some muscles remain paralysed

THE RADIAL NERVE

Owing to its long course its position in relation to the humerus and its peculiar vulnerability to compression paralysis of the radial nerve is one of the commonest peripheral nerve palsies, although it is a mixed nerve containing sensory, motor and vasomotor fibres the symptoms of an injury are almost entirely motor In the upper arm the nerve supplies the triceps and the anconeus in the forearm the supinators the extensors of the wrist and fingers and the extensors and long abductor of the thumb

Injury to the nerve is followed by dropping of the wrist and fingers The wrist and the first phalanges are flexed The flexion is limp and easily reducible

When the lesion is in the axilla the whole of the *triceps* is paralysed and extension at the elbow is lost Occasionally in wounds of the posterior aspect of the arm the nerves to the triceps are injured whilst the main trunk escapes The patient is then able to extend the arm powerfully by means of the anconeus but if he is made to raise the elbow as high as possible with his fingers on the point of the shoulder extension of the bent forearm is impossible

In most cases the nerve is injured in the middle third of the arm and the triceps escapes but the brachio radialis and *all* the extensor muscles in the forearm are paralysed Partial paralyses such as are seen in lesions of the median and ulnar nerves are very rare The brachio radialis is not a supinator Its action is to flex the forearm whilst the hand is in a position intermediate between pronation and supination *Paralysis of this muscle is detected by the absence of contraction when* the pronated forearm is flexed against resistance Owing to paralysis of the *supinator* supination is abolished During the movement of flexion of the forearm the biceps acts as a supinator and during extension the external rotators of the shoulder correspond though feebly

Paralysis of the *extensors of the carpus* abolishes both extension and lateral movement at the wrist The flexors of the carpus play no part in lateral movements The *extensors of the fingers* extend the first phalanges *only* Extension at the distal joints is carried out by the lumbricals and interossei Paralysis of the *extensors and long abductor of the thumb* renders abduction of the thumb and extension of the phalanges impossible On attempting to abduct the thumb it passes no farther than the radial border of the hand In some cases the second phalanx of the thumb can be feebly extended by the muscles of the thenar eminence

Many muscles not supplied by the radial nerve work at a disadvantage when the extensors are paralysed These defects must not be mistaken for signs of injury to other nerves Owing to the flexed position of the hand the grasp is feeble but if the wrist is extended passively the grasp is improved The patient cannot make a fist properly as the thumb does not oppose the index finger and the fingers cannot be flexed into the palm until the thumb has been moved aside by the sound hand The movements of the interossei in abducting and adducting the fingers are also feeble while the wrist is flexed but are much stronger when the hand is resting flat on a table with the wrist and fingers extended The complete reaction of degeneration is often found in all the paralysed muscles from the onset Atrophy becomes obvious in a month or two It *extent and severity give important evidence for prognosis*

Sensory disturbances—Subjective symptoms are rare In a few cases, paræsthesiæ are felt on the posterior aspect of the forearm and on the dorsal aspect of the thumb They are of brief duration and are commoner with partial than with complete lesions Causalgia is almost never seen in lesions of this nerve Sensibility to light touch superficial pain and temperature is impaired over a small area on the radial border of the hand including the proximal joints of the thumb and the first two fingers The defect is often very slight, and is only discovered on very careful examination Deep sensibility is rarely affected Considering the extensive distribution of the superficial branch of the radial nerve it is rather surprising that the sensory disturbances are so slight when the nerve is injured above the origin of this branch

As a rule the brachio radialis recovers first then the extensors of the wrist then the extensors of the middle, ring little and index fingers in this order, and the extensors and abductors of the thumb last of all On palpation of the muscles during attempted extension contractions can be felt before any movement is produced Other signs of impending recovery are the disappearance of automatic pronation and of the flail like drop of the hand, also diminution of automatic flexion of the fingers after passive extension Recovery of movement is complete when the patient is able to extend the wrist and all the fingers simultaneously or separately After this becomes possible restoration of power is rapid

THE MEDIAN NERVE

Whilst the clinical individuality of the radial nerve is shown in the preponderance of motor symptoms and in the uniform completeness of the paralysis that follows an injury that of the median is seen in the frequency of partial and especially of painful lesions Isolated palsy of this nerve is infrequent except as a result of gunshot wounds and other injuries

Total Paralysis—The muscles paralysed are the pronators the radial flexor of the wrist the flexors of the fingers except the ulnar half of the deep flexor most of the muscles of the thenar eminence (opponens abductor brevis and outer head of the flexor brevis pollicis) and the two radial lumbricals Stated briefly the symptoms are inability to flex the phalanges of the index finger and the second phalanx of the thumb difficulty in flexing the phalanges of the middle finger, defective opposition of the thumb The appearance of the hand in total lesions is fairly constant The hand inclines to the ulnar side the index and middle fingers are more extended than is normal and the thumb lies on a level with the fingers—the ape hand

Pronation is incomplete and defective The patient tries to overcome the defect by rotating the whole limb at the shoulder Paralysis of the *flexors of the wrist* is seen when an attempt is made to flex against resistance The tendon of the ulnar flexor alone stands out and the hand is drawn towards the ulnar side Even at rest the flexor tendons are more prominent on the sound than on the affected side

Flexion of the fingers is good in the two ulnar fingers though weaker than normal The index cannot be flexed at all and the third finger only incompletely Flexion at the proximal joint is usually good in all the fingers including the index and flexion at this joint with extension at the last two joints is usually well done by the interossei and lumbricals If the proximal phalanx of the thumb is immobilised it will be seen that flexion of the terminal phalanx is abolished owing to paralysis of the *flexor longus pollicis*

Paralysis of the *thenar muscles* renders opposition and abduction of the thumb defective By means of the adductor the thumb can be drawn into the palm but as the radial fingers cannot be flexed nor the thumb opposed it is impossible to place the tip of the thumb on the tips of the fingers Atrophy of the muscles becomes obvious in a few weeks The outer part of the thenar eminence is flattened and the bulk of the muscles arising from the internal condyle is greatly diminished

Sensory disturbances —In almost every case there is complete anæsthesia to all forms of sensation in the two terminal phalanges of the index and middle fingers The skin outside this area may be unaffected even in complete lesions but in most cases sensibility is diminished in the terminal phalanx of the thumb and to a less extent over the remainder of the radial half of the palm including the radial side of the ring finger The stereognostic sense is lost in the outer fingers This defect together with the loss of power renders the thumb and index finger useless and makes paralysis of the median the most serious single nerve lesion of the upper limb

Vasomotor and trophic changes —In many cases the skin in the distribution of the median nerve is red dry and chapped and the nails white or purple and atrophy occurs in the pulp of the affected fingers

Recovery is slow and is rarely complete Sensation begins to return before power but the stereognostic sense is often defective long after movement in the fingers has returned The pronator and the flexors of the wrist recover first then the flexors of the thumb and middle finger Flexion of the index finger and opposition of the thumb if it is regained at all remains defective for several years In searching for signs of recovery, care must be taken lest some trick movement due to contractions of healthy muscles is misconstrued For example when told to flex the terminal phalanx of the thumb the patient first over extends and abducts and then relaxes suddenly The terminal phalanx then makes a slight passive movement of flexion which may be mistaken for true active flexion Recovery is complete when the patient is able to make a good fist with the fingers flexed well into the palm and the thumb pressed firmly upon the dorsal aspect of the second phalanx of the middle finger

PARTIAL LESIONS —Partial paralysis of the median nerve is much commoner than the complete form

Motor symptoms —Flexion of the index finger and opposition of the thumb are most impaired The flexors of the middle finger and of the terminal phalanx of the thumb may suffer also but to a less degree whilst the pronators and the flexors of the wrist often escape entirely

Sensory symptoms —Apart from the painful lesions to be mentioned later sensory troubles are usually slight in partial lesions Anæsthesia is rare but sensibility to all forms may be diminished in the areas mentioned under complete lesions

Vasomotor symptoms —The skin is often cyanosed in the distribution of the injured nerve and it may perspire more freely than in healthy parts These changes are more distinct when the paralysis is complicated by a vascular lesion

Recovery is naturally more rapid than in complete lesions The order in which the muscles recover and the tests for complete return of function have been mentioned above

PAINFUL LESIONS OF THE MEDIAN NERVE —*Causalgia* —In many cases the most prominent symptom of injury causing an incomplete lesion of the median nerve is *pain* It comes on about a month after the injury at first as tingling or pricking in the finger tips and palm later as a constant severe smarting dragging or *burning* pain—hence the name causalgia Added to the constant pain which never ceases day or night paroxysms occur in which the pain increases suddenly in intensity The application of cold water gives temporary relief and patients often wear bandages or gloves which they keep constantly moistened The pain is greatly aggravated by emotional influences

Vasomotor changes are a feature of this type In many cases perspiration is diminished over the radial half of the palm and the skin becomes dry and scaly In others perspiration is increased over the median area

Motor disturbances are always present but are usually slight the weakness affecting mainly the flexors of the index finger and the thenar muscles

In severe cases the limb is held flexed at the elbow and wrist with the hand

constantly raised and the fingers extended or hyper extended The whole hand atrophies and irreducible ankylosis occurs with the limb in this position The skin of the hand is thin and dry The fingers taper and the nails are long brittle blackened and striated longitudinally The pain reaches its acme 4 or 5 months after the injury and then slowly declines, but the limb remains useless Even in slighter cases without much deformity, recovery of function is extremely slow and is rarely complete The condition is often much improved by early operation and neurolysis of the nerve, or relief may be gained by sympathectomy

THE CARPAL TUNNEL SYNDROME —The median nerve may be compressed at the wrist as it passes through its tunnel in the transverse carpal ligament The condition is common in middle life in women engaged in housework laundrywork and other manual labour and also at an earlier age in women who have young children The chief complaint is of pain or numbness in the middle three fingers but frequently discomfort is complained of also in the forearm and this occurs particularly at night Pressure at the carpal tunnel is thus one of the causes of acroparæsthesia In the more severe cases wasting of the upper part of the thenar eminence may be observed and some sensory impairment may be found over the affected fingers At operation the median nerve is found compressed in its tunnel and swollen for a short distance proximal to its entry into the carpal ligament Opening up the tunnel relieves the symptoms In occasional cases some weakness of the fingers results in consequence of the failure of the weakened carpal ligament to retain the flexor tendons in their normal position

THE ULNAR NERVE

This nerve supplies the ulnar flexor of the wrist the ulnar half of the deep flexor of the fingers the muscles of the hypothenar eminence the interossei the two inner lumbricals and the adductor and inner head of the short flexor of the thumb Its sensory area is the ulnar border of the hand the little finger and the inner half of the ring finger

TOTAL PARALYSIS —Paralysis of the *flexor carpi ulnaris* may be detected by palpating the tendons when the wrists are flexed against resistance The limpness on the affected side contrasts strongly with the firmness on the sound side Lateral movements of the hand are unaffected as these are carried out by the extensors

Paralysis of the ulnar portion of the *flexor profundus digitorum* In making a fist flexion of the index finger is perfect and that of the middle finger good whilst in the ring and little finger it is absent or very feeble This weakness is best seen when flexion is attempted with the index and middle fingers extended Even when the fingers can be flexed by the action of the flexor sublimis the power of resisting passive extension is completely lost in the terminal phalanx of the two ulnar fingers Paralysis of the *hypothenar* muscles abolishes lateral movements of the little finger and diminishes the power of flexion at the proximal joint Paralysis of the interossei and of the inner two lumbricals leads to the production of the claw hand

The action of these muscles is to flex the fingers at the proximal joints with the distal joints extended In the claw hand the posture of the fingers is just the opposite of this namely extension at the proximal joint with flexion of the distal joints Although all the interossei are paralysed the defect is seen only in the ulnar fingers as the radial lumbricals supplied by the median are still healthy It is produced by the action of the long extensors which being now unopposed over extend the proximal joints and by the flexor sublimis which flexes the second joint and draws the distal joint down with it The clawing of the fingers is greatly accentuated when the nerve is paralysed below the point of origin of the fibres to the long flexors of the fingers Other features of the ulnar hand are atrophy of the interossei and of the hypothenar eminence and persistent abduction of the little and ring fingers

The movements of abduction and adduction are lost in the inner two fingers and often in the middle finger Further these fingers cannot be flexed at the distal joint whilst the proximal joints are extended

Paralysis of the *adductor pollicis* and of the inner head of the *flexor brevis pollicis* produces peculiar disturbances in prehensile movements If the patient is asked to grasp a folded paper between his thumb and index finger, and to resist efforts to remove it by pulling it will be found that this movement which is normally very powerful is grossly defective He cannot grasp the object beneath the thumb with the second phalanx extended, but presses the tip of the flexed thumb against the outer margin of the index finger

Sensory disturbances —In complete lesions all forms of sensation are abolished in the little finger and along the ulnar border of the hand Beyond this there is usually diminished sensibility on the ulnar side of the ring finger and over a narrow area towards the centre of the hand on both aspects Spontaneous pains are rare and vasomotor changes are usually slight.

Partial Paralysis —In partial lesions the same symptoms are found in a less degree The small muscles of the hand suffer most Clawing may be slight or absent Neuralgic pains may be felt in the distribution of the ulnar nerve but causalgia is never seen in lesions of this nerve alone

Recovery of sensation is usually complete before movement is regained The flexor carpi ulnaris recovers first then the long flexors of the fingers and last the small muscles of the hand In these recovery is extremely slow When recovery of movement is complete the patient can abduct and adduct the middle finger with the palm flat on a table and he can also scratch the table with the nail of the little finger without moving his wrist.

THE MUSCULO CUTANEOUS NERVE

This is rarely affected alone but is often implicated with the brachial plexus It supplies the biceps coraco brachialis and brachialis Flexion of the forearm can still be carried out by the brachio radialis but the power of flexion is greatly diminished Sensation may be diminished or lost along the radial border of the forearm

THE AXILLARY NERVE

This nerve supplies the deltoid and teres minor, and the skin over the deltoid It may be injured alone in injuries of the shoulder and by pressure of a crutch The chief symptom is paralysis of the deltoid with almost complete inability to raise the arm

In war injuries lesions of the nerves of the lower limb are very frequent but in civil practice apart from sciatica and foot drop local lesions of these nerves are uncommon

THE LUMBO SACRAL PLEXUS

The *lumbar plexus* may be damaged by abdominal tumours and its roots by new growth or other disease of the vertebræ In a certain number of cases signs of inflammation of the lumbar plexus are found in association with sciatica or neuritis of the *sacral plexus*

The *sacral plexus* may be damaged by growths or inflammation in the pelvis by compression during parturition and by penetrating missiles It is also often the seat of spontaneous neuritis

FEMORAL NERVE (L_2 L_3 L_4)

This is the largest branch of the lumbar plexus It supplies the iliacus pectineus sartorius and quadriceps femoris It may be injured alone by fractures of the pelvis or of the femur, by dislocations of the hip or by implication in wounds psoas abscesses or new growths

The *most prominent symptoms* are *loss* of power to extend the knee loss of the knee jerk wasting of the quadriceps and sensory disturbances over the anterior surface of the thigh and inner surface of the leg The psoas always escapes unless the plexus itself is also damaged, but flexion at the hip may be imperfect through paralysis of the iliacus *Owing to the rapid dispersion of the branches in the thigh* wounds in this part often cause partial lesions In these the *nerve to the quadriceps* is most often injured The resulting paralysis causes serious disability in walking as the knee gives way at every step, especially in going down stairs and lameness lasts for a long time after return of voluntary movement

OBTURATOR NERVE (L_2 L_3 L_4)

This nerve is rarely damaged alone It supplies the three adductor muscles the obturator externus and the gracilis The symptoms are weakness of adduction and internal rotation at the hip

LATERAL FEMORAL CUTANEOUS NERVE (L_2 L_3)

This nerve supplies an area of skin on the antero lateral aspect of the thigh As a result of injury but more often without obvious cause the skin in the territory of this nerve may show peculiar sensory disturbances which have been described under the name of *meralgia paræsthetica* Most cases occur in men In women it is usually associated with pregnancy The nerve is tender on pressure at the point where it passes from under Poupart s ligament and neuralgic pain or numbness and tingling is felt in the skin which may be slightly insensitive on objective examination or extremely hyperæsthetic so that the slightest touch causes pain The symptoms which are always unilateral are made worse by walking and may cause serious incapacity by their persistence and severity In severe cases the nerve should be excised

THE SCIATIC NERVE (L_4 L_5 S_1, S S_3)

This supplies the flexors of the leg and all the muscles below the knee It may be involved in pelvic new growths or injured by fractures of the pelvis or femur Next to the radial and ulnar it suffers in gunshot wounds more often than any other nerve

TOTAL PARALYSIS —The foot drops and the toes point downwards Walking is possible but the patient cannot stand on the heel or toes of the paralysed foot The knee is raised high but the steppage is not so marked in total lesions as when the common peroneal alone is paralysed All movement below the knee is abolished When the wound is in the buttocks flexion of the knee is very weak The foot *becomes œdematous if allowed to hang down* *Sweating is often* absent on the sole and dorsum of the foot but is normal on the inner side of the foot which is supplied by the femoral The skin is dry and thin and may be scaly Hyperkeratosis of the sole is common Subjective sensibility is rarely affected The skin is completely anæsthetic over the entire foot except the inner border of the sole and around the internal malleolus The anæsthesia extends upwards on the postero external aspect of the calf in its lower two thirds embracing the tendo Achillis and external malleolus Beyond this area of complete anæsthesia there is a wide zone in which sensibility is diminished The sense of position and passive movement is abolished in the foot and toes The knee jerk is present *The ankle jerk is always lost*

PARTIAL PARALYSIS —In wounds of the sciatic nerve it often happens that the fibres of the common peroneal alone are wounded since the sciatic trunk often divides into the tibial and common peroneal branches as high as the great sciatic notch The symptoms are described below under paralysis of these nerves In other cases the fibres of the tibial nerve are damaged either alone or with some of the fibres of the common peroneal In this case the outstanding clinical features are paralysis of the muscles of the calf and foot anæsthesia of the sole and with incomplete lesions pain similar to that described in partial lesions of the median nerve

COMMON PERONEAL NERVE

This nerve may be injured as it winds round the fibula by wounds or fractures or by compression of a tight bandage The paralysis is usually severe all the muscles being equally affected The foot is dropped and inverted and the toes are slightly flexed Dorsiflexion of the foot extension of the proximal phalanges of the toes and abduction of the foot are impossible The patient can walk and he can stand on tiptoe, but he cannot run and walking is made difficult by the foot drop Subjective sensory disturbances are usually absent The skin is anæsthetic over a narrow band which extends from the outer surface of the leg in its middle third downwards beside the outer border of the tibia and along the middle of the dorsal aspect of the foot as far as the base of the toes For an inch or so, on both sides of this band the sensibility of the skin is diminished The knee jerk and ankle jerk are present The plantar response is always flexor Vasomotor changes are slight and trophic changes are absent

TIBIAL NERVE

This nerve is rarely injured alone It supplies the popliteus the calf muscles the flexors of the toes and the intrinsic muscles of the foot When it is paralysed the patient is unable to stand on tiptoe or to extend or invert the ankle or to flex his toes Paralysis of the interossei leads to a claw like deformity of the foot associated with lowering of the heel and raising of the metatarsus—talipes calcaneo valgus The calf muscles are flabby and the ankle jerk is abolished Sensation is lost on the sole except along its inner border on the outer border of the foot and on the plantar surface of the toes Causalgia similar to that in paralysis of the median is very often present

The distal portion of the tibial nerve may be injured by a penetrating missile or a deep wound in the calf Movements of the ankle are unaffected and anæsthesia is confined to the sole of the foot and heel or merely to its inner half The paralysis of the intrinsic muscles of the foot may escape detection and the lesion may easily be overlooked especially when the nerve is injured below the origin of branches supplying the flexor longus hallucis and the flexor longus digitorum The symptoms then are pain in the sole of the foot anæsthesia on the sole and paralysis of the plantar muscles

Treatment of Local Nerve Lesions—Treatment must depend on the nature and degree of the lesion During the long period which elapses between the onset of paralysis and the first signs of recovery even in cases of simple physiological interruption of the nerves every effort must be made to prevent degeneration of the muscles to keep the circulation of the limb active and to prevent the occurrence of contractures and deformities Massage movements electrotherapy and suitable appliances all have their uses With regard to operative treatment it must be remembered that more than half the cases of nerve injuries undergo spontaneous cure It is advisable therefore to wait 3 or 4 months before an operation is undertaken If at the end of this time the wound is soundly healed and all signs of sepsis have

disappeared, and if as a result of repeated examinations, no sign of recovery has been detected no harm can be done by exposing the nerve If it is found to be divided completely the ends should be "freshened and sutured end to end If the nerve is notched laterally the edges of the notch should be pared and sutured care being taken to preserve the bridge of uninjured tissue Sometimes the nerve at the site of the lesion appears as a fibrous flattened band between two swellings on the nerve In most of such cases the nerve is completely divided, and the condition calls for resection of this fibrous tissue and end to end suture Another common finding, when the nerve is exposed, is a nodule or cicatricial swelling in the course of a nerve which has maintained its continuity In these cases the continuity of the nerve should not be interrupted It should be freed from adhesions and incised in the long axis of the swelling Operations which involve grafting of nerves have met with little success For an account of the advances in the technique of the surgical treatment of nerve injuries which have been made as a result of experience gained in the Wars of 1914–1918 and 1939–1945 special treatises must be consulted

The treatment of painful forms of nerve lesions is extremely difficult In severe cases external applications and internal medication entirely fail Simple freeing of the nerve sometimes gives relief Where this fails, it may be advisable to practise complete division followed by immediate suture In other instances sympathectomy, by excision of the stellate ganglion in the case of the upper limb and of two or more of the lumbar sympathetic ganglia in the case of the lower limb may give lasting relief

INTERSTITIAL NEURITIS

Synonym —*Neuro fibrositis*

Definition —A painful malady which commonly attacks the large nerve plexuses or nerve trunks but which may affect any peripheral nerve, and is believed to be due to inflammation of the interstitial connective tissues which surround and bind together the nerve fibres into the nerve trunks

Ætiology —It is in general a malady of middle life being unknown in childhood and uncommon in old age It is often associated with other forms of fibrositis and especially with arthritis *e g* the brachial nerves being affected in some cases of arthritis of the shoulder and the sciatic nerve in certain cases of arthritis of the hip Injury involving stretching bruising or wounding of a nerve trunk may produce it but it is necessary to bear in mind that pain following an injury even after a long interval may be the result of the rupture of an intervertebral disk which has been injured at the same time Gout diabetes and chronic nephritis are well known clinical associations of interstitial neuritis

Symptoms —These are those of irritation of the nerve fibres Pain is usually the outstanding feature It radiates in the area of distribution of the affected nerve is of a dull aching character with acute exacerbations and is often very long lasting and wearing to the patient The affected nerve is tender to pressure and stretching Subjective peripheral sensations such as tingling burning or numbness are usual and are often the first symptoms There is marked hypotonus of the muscles of the affected limb followed by a degree of general wasting not confined to the muscles supplied by the affected nerve but resembling arthritic muscular atrophy Fibrillation sometimes occurs and cramps are common The deep reflexes of the limb are increased Trophic and vasomotor changes are not infrequent.

Diagnosis —There is often considerable difficulty in the diagnosis of interstitial neuritis on account of the almost identical clinical picture which may occur in the early stages of pressure upon nerve roots or nerves by tumours or as a consequence of the irritation of one or more nerve roots by the extruded nucleus of a ruptured

intervertebral disk The special problems of the sciatic nerve are discussed under the heading of sciatica but the following points are of value in distinguishing in general between interstitial neuritis and the effects of pressure on nerves With pressure lesions the pain is rarely so severe as that of interstitial neuritis tenderness on pressure of the nerve trunks is absent and signs of loss of function—paralysis and sensory loss—come on early The most careful search should be made in every case for any possible cause of local pressure such as primary and secondary neoplasms vertebral and spinal tumours and spinal caries To make a diagnosis of interstitial neuritis in the presence of a mammary or other carcinoma or after its removal is to advocate the highly improbable whatever the symptoms may be

Treatment —The details of treatment vary according to the site of the nerve or nerves affected but the general principles are to secure rest and to avoid all those things which excite or increase the pain In most cases warmth in all forms has a beneficial and comforting effect, the part should be kept warmly clad but if special applications such as radiant heat or infra red rays excite pain they should not be persisted with Salicylates and all the analgesics of the coal tar series are valuable aids In the acute stage morphine preparations may be required to obtain sleep for the patient but later combinations of aspirin with barbiturate hypnotics suffice

CERVICO OCCIPITAL NEURITIS

This condition which is by no means rare is characterised by pain in the upper part of one side of the neck radiating over the branches of the upper cervical plexus the great auricular being the most common and the supra sternal supra clavicular and supra acromial branches less common seats for the pain The fibrositis not infrequently co involves the fibrous structures in the region of the articular and transverse processes giving rise to pain and stiffness of the neck on movement. When the pain is confined to the great occipital distribution alcohol injection is sometimes most efficacious

BRACHIAL NEURITIS

Two varieties of neuritis affect the brachial plexus and its branches namely a paralytic variety and a non paralytic the latter being one of the forms of interstitial neuritis

PARALYTIC BRACHIAL NEURITIS

This variety rare before 1939 has been common in England during recent years and occurred not infrequently in the armies abroad The cause of the condition is unknown but the course of the malady resembles that of an infective disease and in many cases the onset of the neuritis has occurred while the patients were in hospital suffering from an infectious illness of the respiratory or alimentary system

Symptoms —Severe pain in the shoulder or side of the neck radiating down the arm is usually the first symptom but in a few cases no significant pain occurs In the more severe cases general malaise accompanies the onset After a few days paralysis is noticed affecting as a rule some of the more proximal muscles innervated from the brachial plexus Paralysis of the serratus anterior with consequent winging of the scapula is especially frequent and if the patient is in bed because of other symp toms this disability may escape notice until he is up and about again and begins to u e the arm of the affected side If the paralysis affects the muscles of the upper arm wasting is soon evident All the tendon jerks of the affected arm or of both

arms may be abolished Tenderness is present over the brachial plexus and may persist for several weeks Sensory loss is as a rule slight or absent The cerebro spinal fluid is usually normal

Differential Diagnosis —This malady as a rule, only requires to be known about to be recognised, but in subjects of military age or younger the diagnosis has to be made from poliomyelitis In the latter, the onset is more abrupt and in adults is accompanied by a greater degree of malaise and fever, stiffness of the neck is usual and Kernig s sign may be present, the cerebrospinal fluid contains a considerable excess of lymphocytes, followed by a gradual rise of protein during the weeks succeed ing the onset of the paralysis The paralysis tends to have a segmental distribution whereas in the case of brachial neuritis it has much more tendency to be limited to the muscles supplied by one or two individual nerves

Course and Prognosis —In this variety of brachial neuritis the pain usually passes off within a few days and sensory loss if any is soon recovered from, but the outlook as regards recovery of the muscular paralysis is always doubtful, and if such occurs it takes many months

Treatment —The cause of the disease being unknown treatment can only be on general principles Analgesics are given for the relief of pain, and the affected limb is supported in such a position as to relax the paralysed muscles Preparations of vitamin B are often exhibited but it is doubtful whether they are of any value in aiding the recovery of the affected nerves in this disease

INTERSTITIAL BRACHIAL NEURITIS

Ætiology —This variety of brachial neuritis is somewhat uncommon and is met with chiefly in patients over the age of 40 It often arises spontaneously, but is frequently associated with arthritis in the shoulder or neck and it may follow injury to the brachial plexus from any violence causing undue separation of the head and the shoulder

Symptoms —Brachial neuritis of this variety has the general characters of inter stitial neuritis The pain which is often of abrupt onset, may be of great severity and may be at first referred to the region of the plexus itself, the back of the scapula the axilla the forearm or the hand Whatever its site the pain is at first intermittent but it soon becomes continuous and spreads over the whole upper limb Tingling and numbness in the hand and trophic changes in the skin and finger nails are the rule With minimal degrees of this form of brachial neuritis, tingling in the hand in the morning is a common symptom

Diagnosis —It may be impossible to make the diagnosis from brachial pain due to protrusion of one of the intervertebral disks in the lower cervical region (*vide infra*) Other conditions likely to cause confusion are arthritis of the shoulder and cervical rib but in neither of these conditions is there tenderness of the nerve trunks or of the plexus

Treatment —One of the great difficulties in this malady is that in the upright position the weight of the arm and shoulder carries the latter downwards and so stretches the inflamed plexus adding greatly to the pain The patient therefore should be kept in bed and in general on his back Further every movement of the hand or arm tends to increase the pain, and splints which keep the arm in the abducted position and the shoulder raised so as to prevent tension upon the plexus are in valuable

BRACHIAL PAIN DUE TO A PROTRUDING INTERVERTEBRAL DISK

In a considerable number of cases brachial pain which would in the past have been diagnosed with confidence as due to brachial neuritis is in fact the result of irritation of one or more cervical nerve roots by a displaced intervertebral disk

In such cases the onset of pain is usually sudden and often follows forceful movement of the neck or prolonged strain on the cervical muscles with the head partially rotated as may occur in supporting a heavy weight

The pain is usually described as being intense in severity and is felt across the base of the neck and between the shoulder blades and is usually worse on one side It is aggravated by movement or jarring of the neck or by straining

After a few days the cervical pain usually abates somewhat in severity but pain extends down the arm to the digits on one or other side of the hand

When examined the patient is found to have considerable limitation of movement of the neck and may show severe signs of a radicular lesion in the arm in the form of muscular wasting or weakness sensory impairment and diminished reflexes The root most commonly affected is the sixth cervical and the patient s chief complaint is of pain in the arm and pain tingling and numbness in the index finger and to a less degree in the thumb on examination some sensory impairment is found over the index finger and the triceps jerk is diminished or lost and after a time some diminution of the muscles of the forearm is apparent on comparison with the normal limb

Such cases usually recover gradually with symptomatic treatment but some stiffness of the neck may remain Recovery can often be greatly accelerated by manipulation of the neck combined with axial traction which should only be carried out by an expert in manipulative methods

CERVICAL RIBS

Ætiology —The development of the ribs at the thoracic inlet depends on the mode of formation of the brachial plexus for the nerves are large structures in the embryo at a time when the ribs are soft and pliable When the plexus is normal a well formed first rib springs from the first dorsal vertebra If however the plexus is post fixed , that is when the contribution to the plexus from the fourth and fifth cervical segments is small and the fibres from the first and second dorsal segments form a powerful cord this cord in rising over the first dorsal rib may compress and deform it to such an extent that it presents the characters of a rudimentary rib On the other hand and this is more frequent when the plexus is pre fixed that is when the contribution from the upper cervical segments is relatively large and that from the dorsal segments is small a supernumerary rib is allowed to develop from the seventh cervical vertebra When this pre fixation is pronounced the seventh cervical rib is often very large and is easily felt in the neck and in these cases symptoms are usually absent In a certain number of cases in which the abnormality is intermediate in degree symptoms are caused by compression of the lower cord of the plexus as it passes over the supernumerary rib or over the deformed first rib This compression may be exercised by the bony portion of the extra rib but more often the nerves are damaged by a fibrous prolongation of the rudimentary rib which connects it with the first rib

But these abnormalities in the ribs only cause symptoms in some 10 per cent of the cases in which they are present Further the symptoms are often unilateral with bilateral supernumerary ribs and the symptoms are often most prominent on the side of the smaller extra rib Again the onset of symptoms is usually delayed until adult life is reached It is clear therefore that some contributory cause must come into play This is found in the dropping of the shoulder girdle which is normal in adolescents and is often excessive in persons whose muscular tone is low In a child the clavicle rises boldly as it passes outwards In a normal adult male the clavicle is almost horizontal in women it droops slightly and in those who develop symptoms of pressure on the nerves the outer is usually distinctly lower than the inner end

In the latter the lowest cord of the plexus is submitted to constant rubbing against the extra rib which rises and falls during respiration and it is compressed by any movement of the arm which depresses the shoulder girdle Relief is obtained by raising the shoulders and patients soon learn to support the limb and to assume attitudes in which pressure on the nerves is relieved

Women suffer most often the right arm being affected more often than the left The onset is usually gradual but occasionally it comes on suddenly after childbirth, or on lifting a heavy weight

Symptoms—These may be sensory motor or vasomotor, either singly or in combination Subjective sensory disturbances are most frequent. They take the *form of numbness and tingling* or neuralgic pains Paræsthesiæ are most often unilateral and are frequently confined to the ulnar or to the radial side of the hand and fingers It is rare for all the fingers to be affected Pain when present is usually felt below the elbow It is often neuralgic darting down the arm and again confining itself to one border of the limb *It hardly ever radiates from the neck*

Objective sensory disturbances are usually slight or absent They may be found over the ulnar or radial border of the distal portion of the limb in an indefinite area which does not conform to the distribution either of the ulnar or radial nerve

Muscular atrophy is not so frequent as *subjective sensory disturbance* In the "median type", wasting is confined at first to the abductor and opponens pollicis muscles and the outer part of the thenar eminence shows a remarkable reduction in size which contrasts strongly with the inner part, which retains its normal bulk In the ulnar type wasting appears first in the small muscles of the hand supplied by the ulnar nerve In some cases all the muscles of the hand and to a less degree the flexors in the forearm show considerable wasting The atrophy is frequently bilateral and symmetrical

Vasomotor disturbances are very common The hands feel hot or cold, they may be œdematous or discoloured and the changes may suggest Raynaud s disease Pressure on the subclavian artery sometimes causes inequality of the pulse and the pulse on the affected side may be obliterated by depression of the shoulder The inequality disappears when the arm is raised

Diagnosis—The presence of pain paræsthesiæ or vasomotor *disturbances in* the upper limbs or wasting in the muscles of the hands should always arouse the suspicion of supernumerary or rudimentary ribs When pain is the only symptom its distribution along one border of the arm or hand and the patient s account of the manner in which it may be increased or diminished by raising the shoulder girdle or performing movements which depress it usually direct attention to the cause Symmetrical atrophy in the hands may suggest progressive muscular atrophy of spinal origin but this diagnosis is usually rendered untenable by the association of sensory troubles or vasomotor phenomena or by the findings on radiographic examination of the neck For the differential diagnosis from syringomyelia see p 1547 Symptoms indistinguishable from those which commonly result from the presence of a cervical rib occur in a small number of patients in whom no cervical rib is present In most cases of this kind, the patients have very sloping shoulders and the symptoms are believed to be due to *compression of the roots of the brachial plexus between the fibre bundles of the scalenus anterior muscle In other cases either because of the* lowness of the clavicle or because the first rib is unduly high the subclavian artery is compressed between these two bones when the corresponding arm hangs down or when *it is* raised and abducted Obliteration of the circulation causes a numbness in the hand and forearm which comes and goes according to the posture of the arm The numbness may become persistent because of thrombosis at the site of compression and the patient may first come for advice when this has occurred Aneurysm is another occasional consequence of the damage to the artery

Treatment—Pain may be relieved by rest *with the arms suitably supported*

Atrophy calls for operation to remove the offending rib Pain is always relieved by operation either immediately or after an interval of some months The progress of atrophy is always retarded and complete recovery may occur if an operation is under taken early

ACROPARÆSTHESIA

Definition —Acroparæsthesia is the name given to a syndrome of uncomfortable tingling in the extremities without demonstrable sensory loss or other abnormal physical signs

Ætiology —It is unusual for all four limbs to be affected acroparæsthesia in the arms is much commoner than that in the legs In the arms it is almost limited to women whereas in the legs it is much commoner in men There seems to be an hereditary element in its causation As first described it was associated with arthritis and it seems to be commoner in arthritic subjects but both maladies occur in the same age group In both sexes the condition usually comes on in middle life but it also occurs in younger women during pregnancy

Symptoms —The tingling may be present at all times but it occurs above all during the night and wakens the sufferer from sleep some patients complain of the inability to sleep as much as of the discomfort The tingling is in some way due to the use of the limbs during the day in vigorous work or in continuous standing or car driving and if the patient rests throughout the day he or she is as a rule soon relieved of his nocturnal symptoms Many of the patients are middle aged women who have been compelled to do vigorous housework to which they have not been accustomed from youth In general warmth aggravates the tingling and the sufferer who is awakened in the night puts the affected limbs outside the bedclothes In the less severe cases the symptoms are worst during the early part of the night and after a number of hours of broken sleep the patient is able to sleep without interruption for the rest of the night In other cases the symptoms continue throughout the night and are still present in the morning then the hands may appear, or may feel swollen and the patients complain of awkwardness of the fingers but impairment of postural or other sensation can rarely be demonstrated

The symptoms are subject to long remissions but the liability to them is not often completely lost

Diagnosis —There are no objective signs of nervous or vascular disease The most careful examination must be made to exclude such causes of paræsthesiæ as sub acute combined degeneration and early polyneuritis (*e g* diabetic or lead) If the tingling is limited to a part of the hand it may be due to compression of the median nerve in the carpal tunnel or to disturbance of the ulnar nerve or to com pression of a nerve root by an intervertebral disk Slight wasting of muscles may give a clue to the presence of some organic disease The state of the pulses in the affected limbs may suggest the presence of a vascular disturbance to which the symptoms are attributable

Treatment —As has been stated the tingling as a rule ceases if the patient does no work but social circumstances rarely make continued leisure possible the patient may however be able to find more suitable employment or to make changes in his or her habits of work or a holiday particularly with sea-bathing may initiate a remission Sponging the affected limbs with cool water once or twice in the day and possibly at night gives considerable relief in most cases The combination of aspirin gr 10 with phenobarbitone or other hypnotic taken at bedtime enables the patient to sleep

SCIATICA

The term sciatica is applied in a somewhat imprecise manner to conditions in which pain is experienced along the course and in the distribution of the sciatic

nerve—that is to say in the buttock back of the thigh, outer side and back of the leg and the outer border of the foot It is important at the outset to notice the limitations of this distribution and in particular to notice that the sciatic nerve does not supply any structures on the front of the thigh and so pain in that region or in the groin is not included in sciatica

Cases of sciatica as thus defined are common and many of them have a prolonged course and other well described features Until recent years they were all confidently attributed to interstitial neuritis (sciatic neuritis) but it is now recognised that while a number are probably due to this cause many are the result of irritation of one of the roots of the great sciatic nerve by the extruded nucleus of a ruptured intervertebral disk, and others are cases of referred pain in the sciatic distribution The differential diagnosis between these different varieties of sciatica is frequently a matter of great difficulty and in fact in many cases it cannot as yet be made with confidence

SCIATICA DUE TO PROTRUDING INTERVERTEBRAL DISK

Sciatica is the syndrome to which herniation of the nucleus pulposus of a lumbar intervertebral disk most commonly gives rise

Ætiology—The majority of cases give a history of injury at, or shortly before the onset of symptoms The injury is commonly of the variety known as a strain of the back due to sudden bending the lifting of heavy weights or sudden movements of the back as when striving to avoid a fall Males are more commonly affected *In females childbirth especially with instrumental delivery is an additional cause*

Pathology—Formerly the condition under discussion was one recognised on laminectomy, and spoken of as endochondroma of the disk Actually in the circumstances enumerated above the disk ruptures and its nucleus (nucleus pulposus) subsequently herniates into the vertebral canal The commonest site of such a lesion is in the lumbar spine below the termination of the spinal cord and the extruded mass causes irritation and compression of one or more of the roots of the cauda equina The disk most frequently ruptured is that between the fifth lumbar vertebra and the sacrum (fifth lumbar disk) and the spinal root affected is the first sacral The fourth lumbar disk is also commonly ruptured and the third lumbar occasionally so *The rupture of higher lumbar intervertebral disks is infrequent* In each case the spinal root most affected is that emerging just below the site of the lesion *e g* the fifth lumbar root when the fourth lumbar disk is ruptured and so on Multiple ruptures are not very uncommon

Symptoms—The outstanding feature is pain It begins in the small of the back either at the time of the injury or after an interval of some hours days or weeks It may remain limited to the back but in most cases it extends after a variable interval down the back of one thigh and then down into the leg and possibly into the foot so that the clinical condition becomes one of sciatica The exact distribution of the pain in the leg depends on which spinal root is affected (*vide infra*) The pain is *severe and lancinating aggravated by stooping by coughing and sneezing* and by turning in bed and relieved by lying still Flexion of the extended leg at the hip is always painful (Lesegue s sign) and the patient adopts an attitude of partial flexion of the affected limb at the knee and hip which avoids tension on the sciatic nerve and its roots

The objective physical signs fall into two groups namely (1) those referable to the spine and (2) those due to impairment of function in the affected nerve root or roots The lumbar spine is *flattened and is tilted at the site of the lesion* the tilt is usually away from the side of the sciatic pain but may be towards it and in some cases the tilt alternates Radiographic examination reveals the flattening of the lumbar curve and the tilting more clearly and it may show a suggestive reduction of one intervertebral space but this is not usual The nervous signs are in general those

of impairment of function of a single spinal root Most commonly the first sacral root is the one involved and the signs which develop are as follows The ankle jerk is abolished The muscles of the calf and the peronei become slightly wasted and the change in outline is apparent when the two legs are compared with the patient standing up or lying prone The power of flexion of the small toes is diminished The glutei on the affected side are flattened Sensation is impaired along the outer border of the foot and on the outer half of the sole and the patient has a sensation of numbness or tingling in this area The impairment of sensation may be a loss or weakening of pain appreciation and loss of tickle on the affected area of the sole, or a loss of light touch appreciation, or a loss of sense of position of the small toe or all of these combined When the fourth lumbar disk is ruptured and the fifth lumbar root is consequently most affected the site of the worst pain is on the outer side of the leg and perhaps on the dorsum of the foot, wasting of the calf is less pronounced and the ankle jerk is more often diminished than abolished, an area of sensory loss for light touch or impairment of pin prick appreciation may be found on the outer side of the calf In severe cases some disturbances may be found in the functions of the first sacral root as well as in those of the fifth lumbar With lesions of the higher lumbar disks the pain is maximal in the fourth or higher root distributions and the knee jerk may be diminished or lost

It should be borne in mind that in a proportion of cases the nervous symptoms are entirely irritative and consequently objective signs due to impaired root function are lacking Spinal signs are usually present and ultimately some wasting appears but in a number of such cases it is as yet impossible to make the differential diagnosis from sciatic pain due to other causes

Diagnosis —When the diagnosis is in doubt special radiographic examination after injection of Myodil into the theca shows a filling defect in the Myodil shadow corresponding to the knuckle of cartilage indenting the theca This method of investigation is not infallible but in the present state of our knowledge its results should be taken as a practical guide

In almost every case the problem is to distinguish the symptoms of a ruptured intervertebral disk from sciatica due to other causes Most cases of sciatica in people under 40 years of age are due to ruptured discs As age increases other causes assert themselves more strongly but in people who are of athletic type given to such forms of physical activity as gardening horse riding and golf and who are free from arthritis ruptured disk is always a likely cause If there is some history of injury or strain if both the spinal and nervous groups of signs are present and if the latter are limited to the distribution of a single root there is little doubt about the diagnosis In cases of sciatic neuritis tenderness along the line of the sciatic trunk is pronounced and pain and tenderness are seldom limited to the distribution of a single spinal root In cases of referred sciatic pain reflex changes muscular wasting and objective sensory loss are absent Very prolonged and especially recurrent sciaticas are mostly due to ruptured intervertebral disks

Course and Prognosis —In the absence of operative treatment the symptoms usually subside gradually in the course of from 6 weeks to 6 months In a very few cases they clear up more quickly and in quite a number they persist in some degree for years sometimes better and sometimes worse The muscular wasting though obvious never becomes severe and there is never total paralysis of the affected nerve root

Treatment —It is not known how the structures within the vertebral canal adapt themselves but in most instances the pain subsides without operative removal of the protruding mass It is to be presumed that the affected nerve root suffers the minimum of physical irritation when the patient takes up the posture which is for him least painful In general the patient should remain at rest in his most comfortable position and be given such pain relievers of the nature of aspirin veganin and

the like, as may be necessary, together with sedatives if called for In the most acute cases an injection of morphine gr ¼ or pethidine 100 mg may be necessary at night but both these drugs should be used with great care because of the danger of addiction Physiotherapy may be comforting after the acute phase has passed but it is doubtful whether it has any curative effect When the patient has been free from pain for a week while still in bed he may be allowed to sit up and very gradually begin to move about but he should avoid doing anything which causes pain and he should rest when pain begins If pain is recurrent when the patient has begun to move about, support of the lumbar spine by a plaster jacket may give relief

Operation for the removal of the protruding portion of disc is advisable (1) if after 6 weeks or so the pain is not definitely diminished (2) if the sciatica is recurrent (3) if the patient s employment involves heavy work and much movement of the back The operation is not a severe ordeal and most patients are walking again within 3 weeks In general the results are excellent but in some cases some pain persists or returns

REFERRED SCIATIC PAIN

In some cases of sciatic pain there are no manifestations of disease of the sciatic nerve itself either in the way of impaired function or of tenderness and the pain is believed to be a referred pain excited by disease of other structures within the nerve distribution of the spinal segments from which the sciatic nerve arises Such pain is abolished by the cure of the primary disease or anæsthetisation of the structure which it affects Conditions which may give rise to referred sciatic pain are arthritis in the hip joint, arthritis in the sacro iliac joint disease of the lower lumbar vertebræ or of the sacrum, trauma of the gluteal muscles and lesions of the vertebral ligaments It should be noted that malignant disease of the lower vertebral bones may cause severe referred sciatica at a time when no bony change is revealed by radiography and the occurrence of sciatic pain in a patient who has suffered from carcinoma is to be interpreted in the light of this knowledge Elliott and Weddell have shown that the presence of so called rheumatic nodules in the gluteal muscles is not to be regarded as evidence of fibrositis there which might excite sciatic pain because the nodules are due to local muscular spasm consequent upon irritation of nerve fibres, and are not primarily a rheumatic manifestation

Referred sciatic pain is usually moderate in intensity Its distribution is usually in the calf or on the outer side of the leg or on the outer side of the ankle The calf muscles are slightly tender and are the seat of discomfort which causes the patient to make movement of them at frequent intervals The absence of all signs of impaired nervous function has already been mentioned and is the most important diagnostic feature

In all cases of referred sciatic pain the treatment is that of the exciting condition Injection of a local anæsthetic into the disordered structure abolishes the pain temporarily and occasionally the relief is permanent especially if the anæsthetic is used in oily solution the effect of which is more lasting than that of an aqueous solution

OBSTETRICAL PARALYSIS

It is important and useful to group together under this heading all those conditions of paralysis occurring either in mother or child which are the result of the processes of labour in the passage of the fœtal head through the pelvis Autopsies upon the still born and upon children who have survived birth for a few days only have shown that hæmorrhage into the meninges is of common occurrence and it has been argued that such meningeal hæmorrhages are the cause of many of the conditions of cerebral paralysis which are present immediately after birth or which appear during the first

year of life and especially the cause of cerebral diplegia The pathological conditions found in the brain in cases of cerebral diplegia however are such as make it impossible that they could be caused by meningeal hæmorrhage, for no sign of old hæmorrhage is ever found nor could hæmorrhage cause a general cell atrophy of the brain without signs of any local lesion It seems clear, then that though meningeal hæmorrhage may be of common occurrence during birth, and may be the cause of still birth yet there is no clinical or pathological evidence to show that it gives rise to any lasting cerebral defect

The following conditions may occur (1) In the child facial paralysis hemiplegia from laceration of the brain substance fracture-dislocation of the spine with transverse lesion of the spinal cord injury to the brachial plexus from the separation of head and shoulder in traction and injury to peripheral nerve trunks at the elbow, axilla or groin in using traction with the finger

(2) In the mother paralysis of the supply of the lumbo-sacral cord and obturator nerve from prolonged pressure of the head against the sacrum and pelvis.

Facial paralysis —This is usually caused by the pressure of the forceps upon the facial nerve as it crosses the ramus of the jaw but it has been known to occur where instruments have not been used When unilateral as is the common event it gives rise to little or no difficulty with sucking and is evidenced by the unsightly deformity of the face which is drawn over to the sound side When bilateral it is one of the causes of complete inability to suck and on account of the flaccid symmetry of the face may easily be overlooked It necessitates spoon feeding for a considerable time Obstetrical facial paralysis invariably recovers within a few weeks and does not give rise to after contracture Gentle stretching and massage of the face with the finger is the only treatment required

Hemiplegia from laceration of the brain may occur during delivery in contracted pelvis from the pressure upon the sacral promontory and has been caused by the use of *forceps It is exceedingly rare and is generally rapidly fatal from the associated* hæmorrhage It may occasionally be survived with an irreparable hemiplegic condition

Fracture dislocation of the spine is produced by traction upon the aftercoming head by pulling upon the trunk, and it may be associated with injury to the brachial plexus It occurs most often in the lower cervical region and the transverse lesion of the spinal cord is usually complete

Injury to the brachial plexus may occur in traction either upon the head or upon the trunk if the head is aftercoming and is caused by an undue separation of head and shoulder on one side rupturing or straining the brachial plexus The paralysis is usually of the upper arm or Erb type the fifth and sixth roots being most affected, and the deltoid biceps and supinator longus muscles being paralysed but the whole plexus may be involved and even torn completely across Traction upon a prolapsed arm has caused lower arm or Klumpke type of paralysis in which the first dorsal and eighth cervical *roots are most affected* and the intrinsic *hand muscles* and the flexors of the forearm are paralysed The obstetrical lesions of the brachial plexus are for the most part serious lesions many of the cases making no motor recovery at all though sensibility is usually regained The prognosis depends upon the severity of the damage to the plexus as to whether the roots are actually torn or only bruised The slight cases recover well enough

Injury to the peripheral nerves from pressure or traction upon the flexures is seldom severe enough to prevent a rapid and complete recovery

Paralysis of the lumbo sacral cord and of the obturator nerves in the mother immediately after parturition is an exceedingly interesting clinical condition In the first place the lumbo sacral cord is in a much more exposed position as regards the fœtal head engaging the pelvis than are the other nerves of the sacral plexus and may be subjected to such severe pressure as causes paralysis and in the second place

the obturator nerve actually crosses the brim of the pelvis and must of necessity be pressed upon by any large fœtal head which passes the pelvic brim The lumbo-sacral cord paralysis is evidenced by dropped foot and paralysis of the anterior tibial and peroneal muscles and if it is severe by loss of sensibility over the distribution of the fourth and fifth lumbar roots Sometimes the third lumbar root area is affected The obturator nerve involvement is shown by weakness or paralysis of the muscles supplied by the obturator nerve, namely all the adductor muscles of the thigh The paralysis may be noticed directly after parturition or when the patient begins to get about upon her legs The lumbo sacral paralysis is usually unilateral and is nearly always upon the right side The obturator paralysis is not uncommonly bilateral, and both forms of the paralysis may coexist There may be numbness but no pain This condition nearly always occurs with a first delivery, and often the child s head has been unduly large It may recur with subsequent deliveries, but this is not a common event

The *prognosis* is absolutely favourable, every case making a complete recovery in from a few weeks to a few months The treatment is rest in the first place with gentle massage and passive movements, and when power begins to return the patient may commence to get about

POLYNEURITIS

Synonym—Multiple Peripheral Neuritis

Introduction—The clinico pathological condition known as polyneuritis and seen in its most typical form in diphtheritic paralysis or in alcoholic neuritis represents a very striking and uniform reaction of the nervous system Invariably associated with it is a reaction of the myocardium so that there is in cases of polyneuritis a recognised liability to sudden fatal heart failure It is in diphtheritic paralysis and beriberi another form of polyneuritis that this mode of fatal termination is most often seen Indeed beriberi may appear as a rapidly fatal cardiac illness before any signs of involvement of the nervous system have had time to develop

Ætiology—At first sight the factors that give rise to polyneuritis fall into three groups (i) certain chemical poisons (ii) the toxins of certain bacteria and (iii) certain disorders of metabolism Widely differing as these three causative factors may seem to be, there is reason to believe that a common underlying factor which is immediately responsible for polyneuritis may underlie them all It is probable that in the case of groups (i) and (ii) the pathogenic substance gives rise to a disorder of metabolism in the course of which a toxic metabolite is produced in the body this acting as the direct poison for nervous system and heart muscle In the metabolic group (iii) the same process is in action Thus in beriberi for example the illness ensues upon the ingestion of a diet deficient in vitamin B_1 In the absence of this substance carbohydrate metabolism is disordered and a toxic metabolite is produced Thus beriberi is not as the biochemists formerly insisted a starvation degeneration of the nervous system but an intoxication strictly comparable with that obtaining in other varieties ætiologically considered of polyneuritis The final and complete proof of this unity of causation of polyneuritis in whatever circumstances it is seen is not yet available but there is an increasing body of evidence in favour of it

Returning to the ordinary ætiological classifications of polyneuritis we see that in alcoholic or arsenical polyneuritis the poison is taken by the mouth and presumably the final common toxic substance reaches the nervous system by the blood stream In diphtheritic paralysis on the other hand the exotoxins are produced locally at the site of the diphtheritic ulceration whether on the fauces or as in extra faucial diphtheria at some other local site on the body surface This unique channel of entry gives rise in diphtheritic paralysis to a group of symptoms not found in other

ætiological varieties of polyneuritis This group includes palatal and accommodation paralyses which precede the appearance of polyneuritis It is noteworthy that in the case of extrafaucial diphtheria this initial paralysis is not palatal but is anatomically related to the site of the diphtheritic lesion (skin ulceration or wound) Yet the paralysis of accommodation may occur whatever be the site of the diphtheritic lesion It is believed therefore that the exotoxins gain access to the nervous system by conduction from the seat of the lesion via the axones of the nerves which innervate this region They pass upwards in the axis cylinders to the central nervous system and produce their toxic action directly there this action being reflected peripherally again as a motor and sensory paralysis of the muscles and skin (or mucosa) in the region of the lesion Thus a diphtheritic ulcer on a finger may be followed by a local paralysis of that part before polyneuritis develops The subsequently developing polyneuritis is then probably produced in the manner described above while the accommodation paralysis may indicate a specific action of the toxin upon the nervous mechanism concerned We thus have a local a specific and a general group of symptoms The analogy of the local specific and general phases of tetanus will occur to the reader

A peculiar effect of abnormal metabolism is the occurrence of polyneuritis in association with bronchial carcinoma

Acute febrile polyneuritis and Landry s paralysis have no known causal factors They make their appearance in apparently healthy persons adequately nourished and free from all discoverable signs of infection and it is extremely difficult in the present state of knowledge to account for them on any hypothesis of avitaminosis or to suggest any possible mode of intoxication

Many of the intoxications of the nervous system commonly included under the heading of polyneuritis are associated with lesions and clinical manifestations which are not those of polyneuritis Such substances to name but a few are lead, mercury copper carbon disulphide and carbon monoxide and it would be erroneous to regard these as causes of polyneuritis

Pathology —The changes in the nerves are those of parenchymatous neuritis and longitudinal sections stained by the Marchi or Weigert Pal methods show severe degeneration of the fibres The alterations are most intense in the small branches supplying the skin and muscles and they diminish in severity as the larger branches are approached They are best seen in the terminal branches of the musculo spiral and anterior tibial nerves The wasted muscles often show a reduction in the size of their fibres and an increase of connective tissue—fibrous myositis The spinal cord may be healthy but in almost all cases examination by modern methods shows changes in the nerve cells and degeneration in the tract fibres derived from the posterior roots

Symptoms —As might be expected from the composition of the peripheral nerves the symptoms of polyneuritis may consist of disorders of movement sensation and autonomic function and these disorders are symmetrical and typically begin in the peripheral portions of the limbs and spread proximally The relative severity of these disturbances varies from one variety of polyneuritis to another and the detailed symptomatology of each variety is more fully considered below The motor disorder is in all instances a lower motor neurone paralysis with the characteristic weakness, reflex loss and tendency to wasting of the muscles a marked propensity to contracture is universal Bilateral drop foot is in a large number of cases the first objective motor manifestation The sensory disorders are similarly peripheral and symmetrical and may involve both superficial and deep sensibility and may be both positive (pains and paræsthesiæ) and negative (anæsthesiæ) The first complaint is usually of numbness in the feet and in the hands and this extends proximally and is soon accompanied by objective sensory loss which by reason of its mode of development soon has char acteristically a glove and stocking distribution In some varieties the autonomic

defects are seen in alterations in sweat secretion and trophic changes in the skin, nails and other tissues

The tendency to myocardial weakness which has already been mentioned, though characteristic only of certain varieties should be borne in mind in all cases

The cerebrospinal fluid in the infective types of polyneuritis contains an excess —usually a great excess—of protein the globulin fraction also showing an increase, the other elements of the fluid are normal except that in rare cases of acute infective polyneuritis cellular increase may be found

Diagnosis —The diagnosis of polyneuritis from other diseases rarely presents serious difficulty It is made from the combination of symmetrical flaccid paralysis with sensory loss of the "glove and stocking" distribution, and tenderness of the muscles and nerves, confined to or most intense in the distal part of the limbs A variable degree of polyneuritis is an associated feature of subacute combined degeneration of the spinal cord and this disease may easily be confused with polyneuritis The differential clinical features are given on p 1553 and as pointed out there, the distinction at an early stage may in some cases be made with confidence only by examination of the blood for the characters of pernicious anæmia The development of extensor plantar reflexes is an absolute point against polyneuritis while a great excess of protein in the cerebrospinal fluid is equally against subacute combined degeneration When sensory disturbances and diminished tendon reflexes are prominent symptoms and muscular weakness is slight *tabes* may be suggested and the resemblance is still greater when ataxia is present Difficulty usually arises when the distinction has to be made between tabes and alcoholic neuritis in a patient who has courted both diseases In most instances the diagnosis can be made from the nature and distribution of the sensory changes The lightning pains of tabes cannot be mistaken by anyone who is familiar with their peculiar characters Anæsthesia of the extremities is common to both diseases but diminished sensibility around the nose and across the chest is peculiar to tabes and is present in almost every case In neuritis the calf muscles and nerve trunks are tender, whereas in tabes the sensibility of these structures is usually greatly diminished Hyperæsthesia to touch and temperature and great exaggeration of the abdominal reflexes also suggest tabes Examination of the cerebrospinal fluid usually puts the diagnosis beyond doubt.

Rarely does polyneuritis come on with such rapidity as to simulate poliomyelitis When it does so the occurrence of any peripheral sensory loss may reveal its nature, and the absence of cells in the cerebrospinal fluid shows that the illness is not poliomyelitis

Course and Prognosis —In a few instances myocardial failure or respiratory paralysis brings about a fatal issue at the height of the illness Otherwise the normal course of the disease is a stage of invasion followed by a stage of recession leading to complete recovery The duration of these varies greatly according to the ætiology of the malady In rare cases recovery fails to occur and in the chronic hypertrophic types of the disease this is the rule

Disability after recovery from the neuritis may result from muscular contractures wasting or neuritic pains

Treatment —The first essential is to remove the patient from the influence of the exciting cause In alcoholic cases, rigid precautions are necessary to prevent secret access to alcohol To attain this treatment in an institution is almost a necessity In most instances when the cause whatever it may be is removed gradual improvement sets in and complete recovery ensues, in a time that varies with the severity of the symptoms During this time the physician s most important duty is to prevent the occurrence of deformities and contractures From the beginning each joint in the affected limbs should be moved passively to its full range several times each day and care should be taken to ensure that the attitude of the limbs during rest is a suitable one especially that the feet are maintained at right angles to the legs by the use

of appropriate apparatus Drawing up of the heel must be prevented at all costs

Gentle massage is soothing in the acute stage provided muscular tenderness does not preclude it Later more vigorous rubbing may be given and the patient should be encouraged to move the limbs voluntarily Electricity is seldom called for Analgesic drugs and soothing applications may be needed at the onset Thereafter local treatment to the limbs is combined with measures to improve the patient s general condition

The administration of vitamin B_1 preparations has now a great vogue in the treatment of both multiple (parenchymatous) and interstitial neuritis In the latter its use has no theoretical justification or practical value and even in the former though its use is rational it yet remains to be proved that the course of the malady is materially influenced This may be due to inadequacy of dosage in the past, and the parenteral injection for from 2 to 4 weeks of 1000 to 2000 units daily is the minimum dosage likely to be efficacious Even with this dosage it is not yet clear that the course of any ætiological variety of polyneuritis is materially influenced, and extravagant claims should be treated with great reserve

ALCOHOLIC NEURITIS

In former years alcoholism was perhaps the commonest cause of severe peripheral neuritis but at present alcoholic polyneuritis is a rare disease in the British Isles It occurs most often in women especially in those who take small amounts of alcohol frequently and it has often been the first indication of secret drinking There is much evidence that the disorder results as much from the deficient diet and the chronic gastritis commonly found in alcoholic subjects as from the direct toxic effect of the alcohol taken

The onset is insidious, and in most cases premonitory symptoms such as numbness and tingling in the extremities or cramps in the muscles of the lower limbs are present for several months before actual weakness occurs Subjective sensory troubles are a marked feature even in the early stages Besides numbness and tingling the patients complain of feelings of excessive heat or of coldness in the limbs or of severe aching or cutting pains in the legs Painful cramp in the calf muscles is a common symptom It is often worst at night and may interfere seriously with sleep Objective examination usually reveals sensory loss in which the various elements of sensation are affected in a manner which is almost pathognomonic

Stated briefly there is anæsthesia of the skin with hyperæsthesia of the deeper structures Light touches are not appreciated at all or many are missed the temperature sense is defective and the prick of a pin causes no pain whereas even moderate compression of the muscles may cause the patient to cry out The sensory loss is greatest in the feet and hands and diminishes towards the knees and elbows Muscular tenderness is usually greatest in the calves The soles of the feet are also unduly tender Hyperalgesia is often well marked before anæsthesia of the skin appears To the disability caused by pains and spasms weakness of the muscles is added in all but the slightest cases The arms may suffer first but in most cases the extensors of the toes the dorsiflexors of the ankle and the extensors of the fingers and wrists are attacked in progression and double foot drop and wrist drop result To overcome the foot drop the knees are raised high in walking This gives to the gait the steppage character which is common to all forms of peripheral neuritis In most cases the distal flexor muscles are also affected but to a slighter degree In severe cases weakness extends to the proximal muscles and even to the muscles of the trunk The affected muscles become soft and diminish rapidly in bulk Unless precautions are taken, contractures occur in the flexor muscles and produce deformities of the limbs which add greatly to the difficulties of treatment

At the onset the knee jerks are exaggerated but in most cases by the time the patient comes under observation all the tendon reflexes are absent The cutaneous reflexes may be unaltered, diminished or absent Sphincter control is retained Slight bilateral weakness of the face is often present but severe paralysis is rare Ptosis nystagmus and weakness of the external ocular muscles have been observed

Trophic and vasomotor disturbances in the extremities are common The hands and feet often perspire freely at first and then become unnaturally dry, and they may be white and cold or red and hot In some cases œdema of the hands or lower extremities is present In chronic cases the skin of the hands and fingers is thin, smooth and shiny, and the nails are ridged and brittle

In almost every case of alcoholic neuritis there is some *psychical defect* One form—Korsakoff s psychosis—is characteristic of and almost peculiar to this disease The most prominent feature is failure of memory for recent events and loss of appreciation of time and place A patient who has been bedridden in a hospital for nervous diseases for several weeks when visited by the resident physician who has attended her daily will recognise' him at once as Dr X, whom she has not seen since he brought her first child into the world some years ago She is now she says in a lying in hospital which she entered yesterday and has just been confined with her second baby, who is in bed beside her She also recognises strangers at her bedside and connects them with events of long ago Everything is related in the most circumstantial manner, and if the facts were not known her tale might well be accepted as truth In most cases the mental defects are not so gross There is merely a failure of memory, to which is added moroseness and irritability caused by withdrawal of alcohol

ARSENICAL NEURITIS

Peripheral neuritis may be caused by a single large dose of arsenic or it may result from prolonged use of the drug in the treatment of such diseases as Hodgkin s disease chorea and severe anæmia It is a rare malady and the likelihood of its appearing under the last named conditions is negligible The toxic action of arsenic with alcohol seemed to be greater than that of either alone

The description given of alcoholic neuritis applies to this form as well Hyperæsthesia of the skin and tenderness of the muscles are more constant and more severe in the arsenical form and paralysis and atrophy of the muscles are often more wide spread and more rapid in their progress Hyperkeratosis of the soles and pigmentation of the skin are characteristic of arsenical poisoning In a suspected case the diagnosis can be confirmed by the discovery of abnormal quantities of arsenic in the urine or in the hair and skin

The mental changes described in connection with alcoholic neuritis under the heading of Korsakoff s psychosis may be present especially when repeated poisonous doses of arsenic have been taken

DIPHTHERITIC PARALYSIS

The exotoxin of diphtheria is highly selective for nervous tissues and some form of paralysis occurs in a very high proportion of the cases The intensity of the paralysis bears no constant relation to the severity of the local infection for cases in which the original disease has passed unnoticed may be followed by serious damage to the nervous system Walshe has classified the nervous manifestations of diphtheria into three distinct groups namely the local the specific and the generalised paralyses

Local paralysis occurs in parts related anatomically by nervous connections to the site of the diphtheritic lesion In faucial diphtheria the local palsy appears in the palate In extra faucial diphtheria *e g* infected sores on the limbs the local palsy appears in the muscles supplied by the segments of the cord to which afferent nerve

from the infected focus pass The reason for this is that toxins elaborated by the diphtheria bacillus ascend from the primary focus to the cord or the medulla Having reached the central structures they diffuse to neighbouring motor cells and by injuring them cause paralysis of the muscles they supply Paralysis of the palate therefore does not occur except in faucial diphtheria

The *specific manifestation of diphtheria is paralysis of accommodation* Like trismus in tetanus it is not due to a local lesion but occurs in many cases whatever the site of origin of the toxins It is present in cases of both faucial and extra faucial diphtheria and is the local effect of exotoxin accepted from the general blood stream

The third or *generalised* form of diphtheritic paralysis is multiple neuritis It follows extra faucial as well as faucial diphtheria, and is also a result of the action of exotoxin circulating in the blood

As faucial diphtheria is the commonest form the most frequent nervous symptom is *paralysis of the soft palate* It is shown by the nasal quality of the voice and by the regurgitation of fluids through the nose As a rule the weakness is bilateral and equal but in some cases it is greater on the side on which the local lesion is more severe It makes its appearance in most instances about the end of the second week but may come on as early as the fourth day and as late as the sixth week The soft palate is relaxed and its movement on phonation is diminished The palate may be insensitive and its reflex is often diminished or lost Recovery usually occurs in a few weeks In rare instances the muscles of the pharynx and the vocal cords are paralysed Together with palatal palsy it is common to find marked weakness and tenderness of the sternomastoid muscles and masseters These are also local effects

Paralysis of accommodation appears about the same time as the palatal palsy perhaps a few days sooner The reaction of the pupils to accommodation as well as to light can almost always be obtained The trouble is subjective and is shown by defects of near vision—for example by inability to read small print Hypermetropes suffer great inconvenience In myopes it may pass unnoticed Paralysis of any of the extrinsic ocular muscles with strabismus and diplopia may occur and this may be either nuclear or peripheral in type

Multiple neuritis usually comes on 3 to 6 weeks after recovery from the throat infection Its presence is often detected when patients begin to exert themselves during convalescence Weakness and aching pains in the legs unsteadiness in walking clumsiness in performing fine movements with the hands feelings of pins and needles in the extremities—all these are common early symptoms Weakness affects in varying degree the muscles of the neck trunk and limbs It is generally slight in degree greater in the lower than in the upper extremities and greater in the extensor muscles than in the flexors Marked local atrophy is uncommon In severe cases life may be endangered by paralysis of the intercostals and of the diaphragm but fortunately one set of muscles has usually begun to recover before the other is seriously affected The small muscles of the hands and feet and the muscles of the calves and forearms are almost always tender on pressure They are soft and flabby and often show a partial reaction of degeneration

Sensory ataxy is almost always present and is often severe when the paralysis is trivial It causes the patient great inconvenience as it interferes seriously with walking and with the finer movements of the hands Objective examination reveals sensory impairment of the glove and stocking type On the hands and feet the loss to light tactile stimuli is often complete pain and temperature being less affected As the limb is ascended sensation gradually becomes normal Even when the sensibility of the skin is but little diminished the sensations of position and of passive movement in the extremities are often seriously impaired and the sense of vibration is often lost

In the early stages and for a few days the tendon jerks are exaggerated but are lost later in every case Their return is often long delayed, and it is common to see

patients months after recovery of normal power, in whom the knee jerks are still absent It is common also to find them absent many months after an attack of diphtheria in patients who give no history of nervous symptoms during the attack The skin reflexes are usually retained and stimulation of the sole gives a normal response

Cardiac failure is a grave but uncommon complication It is of myocardial origin Vasomotor paralyses and disturbances in the nutrition of the skin which occur so often in other forms of peripheral neuritis are never seen in diphtheria In those that survive the attack complete recovery from the nervous troubles always occurs

ACUTE FEBRILE POLYNEURITIS

Synonym —Acute Infective Polyneuritis

At various times small epidemics of a form of polyneuritis characterised by a febrile onset and by the involvement of the facial nerves have been described (Osler, Gordon Holmes, Rose Bradford and others)

Nothing is known of its ætiology and it is probably not essentially different from Landry's paralysis in nature though less fulminating in onset and not so liable to grave involvement of the trunk muscles

The onset is with slight fever, headache and malaise, pains in back and limbs, and such general symptoms as a coryza or gastro intestinal irritation The fever persists for 2 or 3 days only A few days then elapse before the signs and symptoms of polyneuritis develop It is said that the proximal limb muscles are more severely involved than the distal muscles a point of distinction from other forms of poly neuritis but this relative incidence of weakness is not invariable and has probably been over stressed The trunk muscles do not escape, and the face is often bilaterally paralysed As in other forms the paralysis is of the lower motor neurone type flaccid atrophic and with loss of tendon jerks Sensory loss is very slight, and there is rela tively slight muscular tenderness The cerebrospinal fluid may show a high rise in the protein content but is otherwise normal

The clinical course is variable, and sometimes fluctuating in the individual case Death may ensue from paralysis of the respiratory muscles, but recovery in the majority of cases is fairly rapid There is the usual tachycardia of polyneuritis If the patient survives the acute phase complete recovery ensues

DIABETIC NEURITIS

In many patients with glycosuria symptoms are present which point to changes in the peripheral nerves In some cases the only symptom is neuralgic pain in the distribution of one or more nerves This is commonest in the lower limbs where it simulates sciatica and sugar is found in the urine in the absence of any other sign of diabetes In other cases a single large nerve trunk suddenly becomes paralysed

In severe diabetes the knee jerks and ankle jerks are diminished or lost in more than half the cases This may accompany subjective sensory troubles in the lower limbs or it may appear as an isolated symptom The muscles are very often tender and the vibration sense of the feet is frequently absent To objective examination the sensibility of the skin is usually intact Perforating ulcers of the feet have been observed Only in very rare instances does the neuritis proceed to the stage of general ised peripheral paralysis of motor and sensory structures

PROGRESSIVE HYPERTROPHIC POLYNEURITIS

Dejerine and Sottas described an extremely rare progressive form of polyneuritis sometimes developing in infancy showing an heredo familial incidence and char acterised by thickening of the nerve trunks due to hypertrophy of the sheaths of

Schwann In recent years other cases of hypertrophic polyneuritis have been described which have no hereditary or familial character There is evidence that some at least of the cases described under this heading were examples of primary amyloidosis of the peripheral nervous system

Pathology —The thickening of the nerves may be palpable during life but is not invariably so Microscopically this thickening is found to be due to masses of non nucleated tissue arising from the sheath of Schwann

Symptoms —The malady develops and progresses very slowly with peripheral weakness muscular wasting sensory loss, loss of tendon jerks There may be noted in addition kyphoscoliosis, nystagmus and ataxy of movement It was formerly thought that the Argyll Robertson pupil was an integral part of the symptom complex but this is not the case

Prognosis —Death ultimately ensues from intercurrent disease

Treatment —There is no known treatment which is effective

LEAD PALSY

The nervous effects of lead poisoning are confined almost entirely to motor neurones Subjective sensory disturbances are often slight or absent and in most instances there is no objective sensory loss

Pathology —Aub in 1923 showed that the first event was the local concentration of lead in those muscles which were about to be paralysed and that the paralysis was a muscular event primarily and that secondarily the lead ascends along the motor axons and may finally cause the death of the ventral horn cell The degenerative changes in the nerves are confined almost entirely to the motor fibres and are most intense in the intramuscular twigs supplying muscles of the extensor groups Normal and degenerated fibres are found side by side the former becoming more numerous as the nerve is traced upwards Degenerative changes due to the action of lead are also found in the affected muscles

Symptoms —In most cases of the common *antebrachial* or *wrist drop type*, paralysis is limited to the extensor muscles of the fingers and wrists—that is to the muscles supplied by the musculo spiral nerve But the brachio radialis and the abductor longus pollicis also supplied by this nerve usually escape Inability to extend the first phalanges of the two middle fingers owing to weakness of the common extensor is usually the first difficulty The special extensors of the index and little fingers the long extensors of the thumb and the extensors of the wrist are next attacked and the characteristic wrist drop appears As a rule the paralysis becomes severe about a week after it is first noticed By this time it is usually bilateral and symmetrical but for several days or even for several weeks it may be confined to one side The affected muscles waste rapidly and the back of the forearm becomes flattened thus rendering the intact brachio radialis more prominent In this form loss of power always precedes atrophy and some muscles may show weakness without any wasting Recovery is almost always complete Simple weakness without atrophy usually passes off in a few weeks If the wasting is moderate and the muscles still react to faradism recovery may be expected in a few months When the atrophy is severe a year or more may elapse before recovery is complete

Occasionally the deltoid biceps brachialis and brachio radialis muscles are affected either alone or in company with the forearm muscles—*upper arm* or *brachial type* Less often paralysis occurs in the legs the muscles supplied by the peroneal nerve namely the long extensors of the toes and the peronei being chiefly involved—*peroneal type* Like the brachio radialis in the arm the tibialis anterior although supplied by the peroneal nerve usually escapes This type is usually associated with paralysis of the forearm muscles and runs the same course

In the form of paralysis described above the features are similar to those of a traumatic lesion to a nerve Loss of power precedes, and may be more extensive than wasting faradic irritability of the muscles is lost or diminished while the reaction to galvanism is retained and recovery is usually complete It is therefore called the degenerative form In the second form, the paralysis has the characters of progressive muscular atrophy Weakness and wasting come on together faradic and galvanic irritability of the muscles are both diminished in proportion to the wasting and the paralysis is often permanent This is known as the primary atrophic form. It occurs especially in the small muscles of the hand—*Aran Duchenne type*—but is sometimes irregular in its distribution and affects many muscles in all four limbs It is often associated with the first form but may occur alone Wasting comes on slowly and accompanies the loss of power, instead of succeeding it It is much more intractable than the degenerative form and often persists after muscles showing the first form of paralysis have recovered (See also Lead Encephalopathy p 368)

LANDRY'S PARALYSIS

In the year 1859 Landry applied the name acute ascending paralysis" to a case in which acute flaccid paralysis with loss of reflexes and without sensory disturbances commenced in the periphery of the lower limbs and rapidly spread upwards The arms were next involved, first in the periphery and later the trunk, respiratory muscles neck and lastly the cranial muscles were involved and death occurred from respiratory failure He made a careful microscopic examination of the spinal cord with the methods then at his disposal and failed to detect in it any morbid changes He subsequently described this symptom complex, which has since borne his name from an analysis of ten cases

Since this time a large number of cases have been recorded which from the acute nature of the onset and from the spreading nature of the paralysis have been described as cases of Landry s paralysis This name should be restricted to those cases of acute spreading paralysis in which disorders of sensibility and sphincter trouble are absent or little marked and in which recovery is complete if the patient survives and in which no gross lesion is found within the nervous system after death

Acute poliomyelitis may also in rare cases give rise to a spreading paralysis and cause much difficulty in diagnosis but it is invariable that some permanent paralysis remains upon recovery and further, the lesions of poliomyelitis are both gross and characteristic

Ætiology—What is known of the causation of the disease in general resembles very closely that of acute polyneuritis It affects males much more frequently than females and occurs chiefly in adult life between the ages of 16 and 54 years

Pathology—Slight hyperæmia of the spinal cord and especially of the grey matter with a few punctiform hæmorrhages is the only change noticeable upon naked eye examination Very definite histological changes are found upon microscopic examination in the anterior horn cells and in the cells of Clarke s column, where any degree of change may be found from an early pericentral chromatolysis to a complete loss of the chromatin granules and concentration of nuclei

The cerebrospinal fluid is clear It may present no abnormality either as regards cell or albumin content In other cases there is an excess of albumin and in this respect it resembles the cerebrospinal fluid of polyneuritis which is usually albuminous and sometimes so highly so as to clot spontaneously In a few instances the fluid contains numerous lymphocytes

Symptoms—The onset is in some cases abrupt, with the appearance of the characteristic spreading paralysis Much more frequently the paralysis is preceded by certain premonitory symptoms which may last from a few hours to days or weeks

These symptoms may consist in malaise headache lassitude insomnia anorexia constipation gastralgia vomiting and diarrhœa and there is not infrequently slight elevation of temperature More characteristic still among the prodromal signs are subjective disturbances of sensibility Pains in the back and limbs are common and may be of a dull aching nature or they may be sharp and shooting in character Numbness tingling 'pins and needles' and other paræsthesias may occur over any part of the body and are most commonly complained of in the periphery of the limbs The muscles may be locally tender during this prodromal stage

It is not uncommon for the paralysis to commence in the periphery of the lower extremities to ascend rapidly and to involve the muscles in the order of their innervation from the spinal cord the trunk becoming affected before the upper extremities and the intercostal muscles before the diaphragm The muscular weakness may commence in any group of muscles, as for example in the face neck upper extremities or trunk and when so commencing the spread of the paralysis is downwards constituting a descending type of paralysis

In Landry s paralysis as in acute polyneuritis the innervation of the respiratory muscles seems to be peculiarly resistant to the toxin

In those cases which recover the advance of the paralysis ceases and those muscles which have been most recently affected begin to show some recovery quickly

When the disease does not prove fatal either from respiratory failure pulmonary complications or sudden syncope the paralysis ceases to spread and the patient enters upon the stage of recovery

The paræsthesiæ which have been described with the onset often persist and there may be cramp like pains Not uncommonly the muscles are tender upon deep pressure but there is never that severe degree of tenderness met with in some forms of peripheral neuritis as for example in alcoholic neuritis There is exceptionally blunting of sensibility, most marked in the periphery, but this is never deep and is rapidly transient

Though from the general weakness of the trunk muscles there may be some difficulty in emptying the bladder and rectum during the first few days, and even retention with overflow incontinence that may require catheterisation from the same cause yet these last but a few days The deep and superficial reflexes disappear early with the onset of the first signs of the paralysis in the affected regions The psychic functions remain unimpaired throughout

Diagnosis—The rapidly spreading character of the paralysis in Landry s disease is so striking as to necessitate distinction only from those few maladies in which a similar rapidly spreading paralysis may occur and these are acute spreading myelitis intrathecal hæmorrhage acute poliomyelitis (spreading type) and acute polyneuritis Acute spreading myelitis is at once distinguished from Landry s paralysis by the severe sensory loss and sphincter paralysis which in the former condition develop *pari passu* with the motor paralysis and further if the myelitis does not involve the lumbo sacral enlargement of the spinal cord an extensor plantar reflex will be observed

The rare spreading form of poliomyelitis presents difficulty in diagnosis especially in the acute stage The general symptoms and the pyrexia are apt to be more severe in poliomyelitis An onset in childhood is more suggestive of poliomyelitis than of Landry s paralysis A fairly high polymorphonuclear leucocytosis in the blood and a lymphocytosis in the cerebrospinal fluid are in favour of poliomyelitis The persistence of local atrophic palsy on convalescence is absolute evidence of poliomyelitis The distinction of Landry s paralysis from acute febrile polyneuritis depends on the mode of spread of the paralysis and on the possible presence of numerous cells in the cerebrospinal fluid

Prognosis—In about one half of the cases the paralysis advances until the respiratory and bulbar muscles are involved and death occurs from respiratory failure usually on the third or fourth day but sometimes not until 10 days or more have

elapsed So long as the paralysis is extending and especially when the respiratory and bulbar muscles are failing the prognosis is very grave The extension of the paralysis may however cease at any stage, and when this occurs the prognosis at once becomes favourable even though there be considerable involvement of the respiratory and bulbar muscles

Treatment—The patient must be placed at complete rest and the discomfort and panic which are likely to arise from the utter inability to move must be assiduously relieved by frequent changes of posture The greatest care must be taken that the patient is adequately fed with nutritious and light food Stimulants are usually indicated A mercurial aperient should be administered early and the bowels regularly relieved for in some cases obstinate constipation occurs The bladder should be catheterised, if there is difficulty in micturition Both pain and pyrexia may be relieved by the administration of salicylates or aspirin

Atropine tends to check accumulation of secretion within the bronchi Oxygen may be administered where cyanosis occurs and it may be necessary to place the patient in a Drinker respirator When once there are signs that the malady has passed its height and that recovery is commencing little treatment is required except careful nursing and feeding Gentle massage may then be employed

MUSCULAR DISEASES

PRIMARY MUSCULAR DYSTROPHIES

Synonym—The Myopathies

Under this heading a disease is described in which the voluntary muscles undergo primary degeneration independent of detectable disease in other parts To facilitate description a number of clinical types have been distinguished according to the age at which the disease appears to the group of muscles first attacked to the presence or absence of pseudo hypertrophy and to the prominence of the hereditary factor The chief of these are—(1) the pseudo hypertrophic type (2) the juvenile type of Erb (3) the facio scapulo humeral type of Landouzy and Dejerine (4) the distal type

The first type is fairly constant but there is in reality no sharp division between the different forms That the others do not represent separate diseases is proved by the appearance of more than one of them in members of the same family The disease is familial and it is also hereditary in the sense that it may appear in some or all the members of a family through several generations

The changes in the muscles in the myopathies are essentially the same as those which occur when muscles degenerate from any other cause namely a slow and progressive atrophy of the contractile elements with a concurrent increase of fat and fibrous tissue However in most cases of myopathy swelling or hypertrophy of some of the muscle fibres is a feature of the microscopic picture and this hypertrophy is believed to represent an early stage of the degenerative process In the pseudo hypertrophic form the connective tissue hyperplasia is excessive in some of the affected muscles and their bulk is increased In the other forms of the disease and in those muscles in the pseudo hypertrophic form which become weak without any increase in size the overgrowth of connective tissue may balance the loss of bulk due to atrophy of the contractile tissues and the diseased muscles retain their normal size or atrophy may proceed faster than hyperplasia and the muscles waste from the beginning

1 PSEUDO-HYPERTROPHIC MUSCULAR DYSTROPHY

Ætiology—The cause of the disease is unknown In many instances no antecedent cases can be traced in the family In others a family history is obtained

always on the mother s side Isolated cases occur but more often several children are attacked in each generation Boys suffer more frequently than girls in a propor tion of about 5 to 1 Sometimes one sex alone suffers sometimes both It is rare for all the children to be attacked The males who escape beget healthy children whilst the females who appear to have escaped may transmit the disease to some of their offspring

Symptoms —The symptoms appear in early childhood The onset is often delayed to the fourth or fifth year rarely until towards puberty and very rarely until as late as the twentieth year In cases of late onset enlargement of the calves has usually been present for many years Weakness appears first in the muscles of the pelvic girdle The child who usually looks fat and strong begins to walk late he falls easily and rises again with difficulty He does not romp as other children do He cannot skip or jump and he has great difficulty in mounting stairs At first the muscles may be normal in size but as a rule some show obvious enlargement before the fifth year is reached The enlargement is most conspicuous in the calves the buttocks and the infraspinati The erector spinæ the quadriceps in whole or part the deltoid the supraspinatus and the triceps often show considerable hypertrophy Occasionally the masseters are enlarged At the same time other groups of muscles atrophy This is most severe and most frequent in the latissimus dorsi and in the lower part of the pectoralis major Later it extends to other muscles and ultimately to those which were at first hypertrophied The neck and face are spared There is no exact correlation between the size of the diseased muscles and their power but weakness is usually greatest in those which show most atrophy The defects are greater in the proximal muscles and diminish distally The hands often retain good power to the end This distribution of paralysis gives rise to certain character istic defects of attitude and movement.

In standing the legs are placed far apart and the upper part of the trunk is thrown back so that a plumb line from the most prominent vertebra falls behind the sacrum This attitude compensates for the forward tilting of the pelvis resulting from weakness of the glutei which normally raise the anterior border of the pelvis by lowering its posterior border In the sitting posture the lordosis disappears for now the attach ments of the flexors of the hip are approximated and these muscles no longer lower the anterior border of the pelvis On lying down the lordosis appears again, but can be abolished by relaxing the flexors of the hip joint, that is by flexing the hips passively In walking the feet are widely separated and to clear the ground with the advancing foot the body is inclined first to one side and then to the other This waddling produces a gait like that seen in congenital dislocation of the hip The early preponderance of weakness in the extensors of the hip and knee is betrayed by the great difficulty experienced in mounting stairs

The manner in which the child rises from the supine to the erect position is almost pathognomonic of the disease He first tries to sit up but fails He then rolls over on his belly and raises himself first on his knees and elbows and then on his hands and feet Next he places his hands on his knees and as it is impossible for him to raise the trunk actively owing to weakness of the extensors of the hip he literally climbs up his thighs Pushing the extensors may be enough to enable him to complete the movement if not he jerks the shoulders back suddenly and gains the erect posture by a writhing movement whose details are difficult to follow To climb the thighs successfully a certain amount of power is necessary to hold the knees slightly flexed When this power is lost he is no longer able to rise The arms are also used to assist the weak legs in sitting down and in getting up from a chair

As time goes on the weakness increases and invades all the muscles of the trunk and limbs Some of the muscles become shortened and distortions are produced by permanent alterations in the position of the joints The knees and elbows become

flexed, the feet take up the attitude of *talipes equinus* the spine becomes curved and the whole body is grossly deformed

The deep reflexes and the electrical excitability of the muscles diminish gradually as the wasting increases Sensation is unaffected The sphincters are not involved. The mental condition shows no abnormality

Diagnosis —The diagnosis is usually simple if a few of the outstanding features of the disease are known The defects of attitude and movement especially the mode of rising from the supine position, together with the characteristic association of enlargement of the infraspinati and calves with atrophy of the latissimus dorsi, form an unmistakable combination

Prognosis —This is most grave Few patients reach adult life, and most die within 10 years of the onset of the disease

Treatment —Drugs have no beneficial influence Glycine in large doses has been advocated but there is no reliable evidence that it affects the course of the disease Massage and passive movement are useful in the prevention of contractures and the efficiency of the muscles may be prolonged by suitable exercises Walking should be practised daily until it becomes impossible Very often this is lost owing to contractions of the calf muscles and is regained after tenotomy

2 OTHER TYPES OF MUSCULAR DYSTROPHY

Ætiology —The separation of the remaining types of myopathy from the pseudo hypertrophic form is not an absolute one, as isolated cases are occasionally met with which seem to form a connecting link between the several varieties The varieties however are habitually separate in occurrence and in families in which numerous cases conforming to the types to be described hereunder have occurred throughout several generations no cases presented the peculiar features of the pseudo hyper trophic form Moreover the sex incidence as well as the period of onset is different in the two varieties and it is possible that there is some essential pathological difference between them and that they are separate diseases With regard to the types of myopathy unassociated with pseudo hypertrophy no doubt exists as to their fundamental unity They are merely varieties of one disease

The influence of heredity is much more prominent than in the pseudo hypertrophic form Isolated cases occur, but they are rare In most instances several members of a family are affected in the same and in succeeding generations

The sexes suffer equally The time of onset varies within wide limits—from infancy to old age When the wasting begins in the face (*facio scapulo humeral type*) the disease frequently begins in childhood but sometimes it begins there late in life In the cases where it is first noticed in the muscles of the shoulder and pelvic girdle the onset is most frequent between the ages of 15 and 35 (*Erb s juvenile type*) but here again it may begin in childhood or early old age and the term juvenile is hardly applicable to it The same variations in the age of onset are noticeable in cases where the atrophy begins in the forearms and legs (*distal type*)

The various types may be exemplified in members of the same family and in the same family the age of onset may show extreme variation

The cause of the disease is quite unknown

Symptoms —In the so called juvenile form weakness and wasting come on simultaneously In most cases they are first noticed in the arms but in some families the legs suffer first Of the arm muscles the biceps triceps and brachio radialis are most often first affected The lower part of the pectoralis major the latissimus dorsi trapezius and rhomboids are attacked in most cases Atrophy of the serratus magnus is common, but it may escape even in severe cases The deltoid supra spinatus infraspinatus and subscapularis usually escape Atrophy of the forearm and hand muscles is rare

In the legs, the flexors of the hip the extensors of the knee and the glutei are most frequently affected The muscles below the knee often escape entirely

In the face the zygomatic muscles and the orbiculàris are attacked The face is dull and expressionless the naso labial fold is obliterated the lips are habitually separated and the lower lip projects—myopathic facies The face does not light up in conversation in blinking the eyes are incompletely closed and the articulation of labial consonants is defective In smiling the mouth forms a straight line instead of its angles being drawn upwards and outwards by the zygomatici The power of whistling is lost When the patient closes his eyes or compresses his lips as forcibly as he can they can be forced open with great ease The buccinators are often affected the tongue and the masticatory muscles never The spinal muscles often atrophy and in a few cases the abdominal muscles have been involved The excitability of the muscles to faradic and galvanic stimulation usually diminishes in proportion to the wasting The muscles never show fibrillary tremors Sensibility is unaffected and all the other functions of the nervous system are normal Deformities are neither so common nor so severe as in the pseudo hypertrophic form

Diagnosis —In isolated cases the diagnosis of myopathy from spinal progressive muscular atrophy is based upon the distribution of the wasting upon the disproportionate weakness and the absence of fibrillation in the affected muscles and the age of the patient When a family history of atrophy is obtained dystrophia myotonica and peroneal muscular atrophy must be excluded Dystrophia myotonica is distinguished by the peculiar prolonged response of some of the muscles to voluntary electrical and mechanical stimulation and by the distribution of the wasting Atrophy of the sterno mastoids which is constant and severe in dystrophia myotonica is never seen in the forms of myopathy now under consideration In peroneal muscular atrophy the combination of atrophy in the lower limbs and small muscles of the hands together with sensory disturbances in the lower limbs is distinctive In an early case when the hand muscles are still normal and sensory changes are absent the differentiation from myopathy may be impossible for a time

Prognosis —The disease shows wide variations in its course and duration The atrophy may remain confined to the group of muscles in which it begins or extension may take place after an interval of several years It rarely extends beyond the muscles mentioned above In most cases even in those that begin in childhood progress is extremely slow and as no symptom of the disease is necessarily fatal death usually results from other maladies unconnected with the disease

Treatment —Owing to the variable course of the disease it is impossible to estimate the value of any treatment that may be employed Massage and especially voluntary exercises designed to bring the weakened muscles into play seem sometimes to retard the progress of the disease

AMYOTONIA CONGENITA

Synonyms —Oppenheim s Disease Myotonia Congenita

Definition —A malady of early childhood usually congenital and sometimes familial characterised by extreme flaccidity smallness and weakness of the muscles which are not actually paralysed by lowering of the faradic excitability of the muscles by loss of the tendon jerks and by contractures in the region affected

Ætiology —In most cases the disease is present at the time of birth in a few cases it has appeared during the first year of life in an apparently healthy child and sometimes following an acute illness such as bronchitis or diarrhœa Usually sporadic, it has occurred in several children of the same parents Some authorities consider that it is a variant of the Werdnig Hoffmann disease (*q v*) (p 1565)

Pathology —The chief morbid changes are found in the muscles In these very

conspicuous pathological conditions are present, closely resembling those found in the myopathies The three most striking conditions are—(1) the minute size of the majority of the muscle fibres from 7μ to 12μ (2) the presence of a few very large or giant " fibres reaching 140μ in diameter, and larger than any fibre occurring in normal muscle, (3) marked regressive changes in the giant fibres There is increase of the connective tissue between the muscle bundles Reduction in numbers of the ventral horn cells of the spinal cord occurs and the ventral roots are small and poorly myelinated

Symptoms—The extreme flaccidity of the affected muscles is noticed from the time of birth They are small and weak, and though there is no muscular wasting and no absolute paralysis, yet in many cases the limbs cannot be raised against the action of gravity, nor can the head be held up The great relaxation of the muscles and ligaments allows of the most fantastic attitudes being assumed without pain When the child gets older, he is unable to sit up but when placed in the sitting position the spine bunches up from absence of any muscular support and he is unable to support his weight upon the weak legs The amyotonia is symmetrical and affects the legs always the trunk often the arms not infrequently but never the face Notwithstanding the flaccidity some degree of flexor contracture is usually present The faradic excitability of the muscles is much lowered but not lost Sensibility and the sphincters are not affected The superficial reflexes are normal but the deep reflexes are invariably absent in the affected regions The children are usually intelligent with good bodily development and growth proceeds normally

Diagnosis—This presents no difficulty on account of the presence of the flaccidity at birth the absence of the deep reflexes and the tendency slowly to improve It has to be separated from those maladies to which it bears a superficial resemblance namely the myopathies rickety weakness, obstetrical infantile and diphtherial palsies

Course and Prognosis—Some of the children succumb during the early and severe stages of the disease but the tendency of the disease is to improve slowly in the course of years and in some cases almost complete recovery with return of the knee jerks occurs

Treatment—This consists in aiding the natural tendency to improve with massage passive movements and exercises in treating contractures with tenotomy and in attending to the general health and nutrition

DYSTROPHIA MYOTONICA

Synonym—Myotonia Atrophica

Definition—A disease of familial incidence which begins usually in the third and fourth decades of life and which is characterised by muscular atrophy of peculiar distribution and unlike that of any other disease This atrophy occurs first and most in the sterno mastoids and facial muscles next in the muscles of the forearms and may also be found in the muscles of mastication in the vasti and in the dorsiflexors of the feet and peronei Associated with this wasting but not commensurate with it nor necessarily occurring in the same muscles is a peculiar difficulty in relaxing the muscles after effort called myotonia which gives to this malady an especial feature which at once separates it from all other forms of muscular atrophy Signs of bodily dyscrasia are often present the most important of which are cataract premature baldness atrophy of testicles loss of sexual power and general bodily wasting This disease was first placed upon a firm clinical basis by Batten and Gibb and Steinert in 1909 Curschmann in 1912 adopted the term Dystrophia Myotonica as being more correctly descriptive

Ætiology—This condition is probably always familial and the heredity is homologous—that is it tends to appear in the same child rank in a number of

apparently unconnected families at a common distance from one and the same ancestor and often it seems to be entirely confined to one child rank The descent of the latent tendency is equally through the males and females but the males more frequently transmit The presence of the heredo familial disease in earlier generations is often betrayed by other signs such as cataract frequent celibacy childless marriages high infant mortality and a dying out of certain branches of the family The malady has been observed at the age of 10 years but usually the onset occurs between the ages of 20 and 35 years A large number of the patients have been unusually gifted and proficient in athletics prior to the onset Both sexes may be affected No exciting causal factors are known

Pathology —No definite changes have been found in the nervous system The muscles presenting the myotonia have repeatedly been examined and found normal In the atrophic muscles the morbid process singles out certain fibres especially so that thick and thin fibres are found lying together There is increase of the muscle nuclei round thick and thin fibres alike though some atrophic fibres may be found with no increase of nuclei Recent biochemical and electrographic studies by Brown and Harvey of a form of congenital myotonia in goats suggest that there is no functional disorder of neuromuscular transmission of the motor impulse but that the disorder is in the muscles themselves

Symptoms —The onset is gradual and the course extremely slow The first symptom to call attention may be either the difficulty in relaxing after muscular effort—the clinging of the hand to the tool which has been grasped the smile that is so slow to disappear—or the weakness and wasting of the muscles The two chief signs of the disease—the myotonia and the wasting—seem to have no connection the one with the other either as regards coincidence in time or place The myotonia may appear years before there is any obvious wasting Moreover the muscles which show the most conspicuous myotonia are often those which are not wasted and finally those muscles which waste greatly tend to lose any sign of myotonia which they may have had The extent and the intensity of the muscular atrophy and of the myotonia show great variations The atrophy may be widely spread and many muscles may be myotonic or the former may be severe and the myotonia slight or both may be present in minor degree only Lastly there are cases in which only the atrophy or only the myotonia is present The myotonia consists in an inability to relax a muscle immediately after it has been put into voluntary contraction and the greater the effort used in contracting the muscle the greater the difficulty with relaxation The patient grasps one by the hand and is unable to disengage the hand but pulls it away still grasping and it may take seconds to relax He smiles quickly to a suitable stimulus and the face remains fixed at the height of the smile for long after the emotion has vanished In eating his jaw becomes fixed he is unable to perform alternating movements in the muscles which are affected except at a very slow rate When the myotonia is severe and general he is liable to fall like a log when walking from inability to relax muscles which have been put into contraction The myotonia is seen most often and to a greater extent in the flexor muscles of the forearm and in those of the face but it may be quite general In the same patient it may be very marked at one time and absent at another The muscular weakness and wasting usually have a most typical distribution involving the sternomastoids and other muscles of the neck the facial and masticatory muscles—giving rise to the sad myopathic face the vasti of the thighs the dorsiflexors of the feet and the flexor muscles of the forearms and this is the usual order in which the muscles are affected It is always in one or other of these groups that the wasting commences but sometimes the sequence of muscles attacked is quite different Fibrillation does not accompany the atrophy The electrical reactions show a reduction both to faradic and to galvanic stimuli with a tendency to a polar change The myotonic reaction consists in a very long lasting contraction when the muscles are stimulated with every

conspicuous pathological conditions are present, closely resembling those found in the myopathies The three most striking conditions are—(1) the minute size of the majority of the muscle fibres, from 7μ to 12μ (2) the presence of a few very large or giant' fibres reaching 140μ in diameter and larger than any fibre occurring in normal muscle (3) marked regressive changes in the giant fibres There is increase of the connective tissue between the muscle bundles Reduction in numbers of the ventral horn cells of the spinal cord occurs and the ventral roots are small and poorly myelinated

Symptoms —The extreme flaccidity of the affected muscles is noticed from the time of birth They are small and weak and though there is no muscular wasting and no absolute paralysis yet in many cases the limbs cannot be raised against the action of gravity nor can the head be held up The great relaxation of the muscles and ligaments allows of the most fantastic attitudes being assumed without pain When the child gets older he is unable to sit up but when placed in the sitting position the spine bunches up from absence of any muscular support and he is unable to support his weight upon the weak legs The amyotonia is symmetrical and affects the legs always the trunk often the arms not infrequently but never the face Notwithstanding the flaccidity some degree of flexor contracture is usually present The faradic excitability of the muscles is much lowered but not lost Sensibility and the sphincters are not affected The superficial reflexes are normal but the deep reflexes are invariably absent in the affected regions The children are usually intelligent with good bodily development and growth proceeds normally

Diagnosis —This presents no difficulty on account of the presence of the flaccidity at birth the absence of the deep reflexes and the tendency slowly to improve It has to be separated from those maladies to which it bears a superficial resemblance namely the myopathies, rickety weakness obstetrical infantile and diphtherial palsies

Course and Prognosis —Some of the children succumb during the early and severe stages of the disease but the tendency of the disease is to improve slowly in the course of years and in some cases almost complete recovery with return of the knee jerks occurs

Treatment —This consists in aiding the natural tendency to improve with massage passive movements and exercises in treating contractures with tenotomy and in attending to the general health and nutrition

DYSTROPHIA MYOTONICA

Synonym —Myotonia Atrophica

Definition —A disease of familial incidence which begins usually in the third and fourth decades of life and which is characterised by muscular atrophy of peculiar distribution and unlike that of any other disease This atrophy occurs first and most in the sterno mastoids and facial muscles next in the muscles of the forearms and may also be found in the muscles of mastication in the vasti and in the dorsiflexors of the feet and peronei Associated with this wasting but not commensurate with it nor necessarily occurring in the same muscles is a peculiar difficulty in relaxing the muscles after effort, called myotonia which gives to this malady an especial feature which at once separates it from all other forms of muscular atrophy Signs of bodily dyscrasia are often present the most important of which are cataract pre mature baldness atrophy of testicles loss of sexual power and general bodily wasting This disease was first placed upon a firm clinical basis by Batten and Gibb and Steinert in 1909 Curschmann in 1912 adopted the term Dystrophia Myotonica as being more correctly descriptive

Ætiology —This condition is probably always familial and the heredity is homologous—that is it tends to appear in the same child rank in a number of

Ætiology—Beyond the facts that the malady is usually hereditary and familial only a few sporadic cases occurring and its incidence in early childhood nothing is known of the causes Cold heat fatigue and hunger conspicuously increase the symptoms

Pathology—The affected muscles are actually hypertrophied and are always *firmer to the feel than normal muscles while sometimes they show a board like hard*ness The individual fibres show considerable hypertrophy

Symptoms—The presence of the disease first becomes evident from slowness clumsiness and awkwardness of movement with a great tendency to fall if the balance is upset This is often most noticeable after rest when on attempting to move the limbs seem glued down and move very slowly Often the patient is able with exercise to work the stiffness off and the myotonia lessens in the muscles which are being used but if he is suddenly called upon to put another set of muscles into action as for example by losing his balance he is at once caught up by the myotonia and so is apt to fall In other cases the myotonia increases or is uninfluenced by exertion The muscles of the legs are as a rule most affected but sometimes all the muscles of the body may be involved

Passive movement does not reveal the presence of any rigidity The abnormality affects only the relaxation of the muscles after voluntary contraction the peculiar feature being the slowness of relaxation due to the continuance of the contraction of the muscle fibres for a variable number of seconds after voluntary impulses have ceased The peculiarities of electrical excitability bear the name of the myotonic reaction of Erb The contraction either on faradic or galvanic stimulation lasts much longer than the normal and relaxes very slowly and this is more marked the stronger the current used with the application of galvanism slow wave like contractions of the muscle are seen to proceed slowly from the cathode to the anode There is no pain no sensory disturbances or loss and the sphincters and reflexes are unaffected

Diagnosis—The only malady which can be confused with Thomsen s disease is dystrophia myotonica in which the myotonic symptoms and signs are identical In the latter malady the onset is at a much later age the incidence of the spasm is upon local groups of muscles and the characteristic weakness of the facial muscles and atrophy of the sternomastoids etc at once distinguish it

Course and Prognosis—Thomsen s disease has no tendency to shorten and destroy life It tends to become more marked from infancy to puberty and then less marked again as age increases It has never been known to recover spontaneously

Treatment—No cure for the disease is at present known The administration of quinine hydrochloride in doses of gr 10 to gr 15 by mouth t d s may give considerable symptomatic relief Conditions which increase the myotonia such as cold fatigue and hunger should be avoided Most patients are the better for regular exercise as was observed by Thomsen who was himself afflicted with the disease

MYASTHENIA GRAVIS

Definition—A chronic malady of adult life characterised by an excessive fatiguability of the voluntary muscles especially those innervated by the cranial nerves This leads to a variable paralysis of the muscles concerned which is brought on or rapidly increased by exertion and tends to improve with rest but which may ultimately become permanent

Ætiology—The malady seems to have become more prevalent in this country *during the past 30 years It affects predominantly* young adults between the ages of 20 and 30 It very rarely occurs before puberty but cases beginning in middle or late life are by no means as uncommon as was formerly supposed The sexes

form of stimulus and if the latter be strong it may last as long as 30 seconds This is usually present in the muscles which are myotonic and not wasted and some modification of it is often superadded to the other electrical changes in those muscles which are wasted

The affection of the muscles of the face and jaw entails some alteration of articulation and phonation The voice is low, it lacks intonation and has a definite nasal quality Sensibility is not affected

The rule is for the tendon jerks to be diminished or lost and it is very rare for all the jerks to be present in any case

Apart from symptoms and signs connected with the muscles the most important sign of the dystrophy is cataract which occurs in more than half of the cases This cataract is often met with in otherwise healthy brothers and sisters of those who have the muscular changes and in otherwise healthy members of earlier generations in the afflicted families In succeeding generations after its first appearance the age of occurrence of this cataract shows remarkable anticipation'—that is commencing at first as senile cataract it appears at an earlier and earlier age with each successive generation until with fully developed myotonia atrophica it appears in youth The presenile cataract of the dystrophic generation begins as small peripheral opacities first in the posterior and later in the anterior cortical lamellæ sometimes with fine point like opacities scattered through the lens It ripens quickly to a total soft cataract, with a small central nucleus

The genital organs remain infantile in some cases celibacy and childless marriages are common More often sexuality is normal until the onset of definite symptoms after which desire and power disappear, and ultimate atrophy of the testicles is usual Early frontal baldness is the rule A general wasting of all the tissues of the body is seen in many cases

Diagnosis—There is no difficulty in the diagnosis when the distribution of the muscular atrophy is typical and when myotonia is obvious it simply involves a recognition of the unique characteristics of the disease When the myotonia precedes the wasting the age of onset will distinguish this malady from Thomsen s disease myotonia congenita and the oncoming of any sign of facial weakness or muscular wasting will make the diagnosis certain When the myotonia does not appear until long after the wasting is apparent the diagnosis is much more difficult, but the wasting of the sternomastoids is characteristic

Course and Prognosis—This malady usually progresses very slowly but occasionally very extensive and incapacitating wasting of muscles and weakness may develop within a year of the first symptom Some cases seem to remain stationary for very long periods The tenure of life is certainly short in all cases and does not appear to be prolonged beyond the middle of the fifth decade The oldest patient reported in the records as still living was aged 50 years

Treatment—It has been found that the administration of quinine gr 10 to 15 daily lessens the myotonia considerably Neither electrical treatment nor massage has the slightest effect in altering the course of the disease

MYOTONIA CONGENITA

Synonym—Thomsen s Disease

Definition—A very rare malady commencing in early childhood which is hereditary and familial and characterised by a striking slowness in the relaxation of the muscle after voluntary effort On voluntary contraction the muscles pass into a spasm which relaxes very slowly resembling the contraction of the veratrinised frog s muscle and its subsequent slow relaxation Peculiar changes in the electrical excitability of the muscle and hypertrophy of the muscle fibres are constant

may give rise to so much fatigue of the masticatory muscles that only soft foods can be taken and towards the end of a meal the lower jaw may be too heavy for the exhausted muscles to sustain and the patient may be seen supporting it with the hand and attempting in this way to supplement the process of mastication The muscles of the face commonly share the weakness Friends observe that towards the end of the day the patient s face is expressionless or comment on the peculiar snarling quality of the smile The patient may complain that he cannot smoke a cigarette or whistle as the lips cannot maintain a sustained pressure In severe cases the eyelids can only be closed with difficulty and it may be noticed that the patient sleeps with the eyes open Fatigue of the neck muscles may be an early symptom The head feels more and more heavy and finally can only be supported with the aid of the hand The weakness may affect any or all of the muscles of the limbs and trunk though the arms are more frequently involved than the legs The soldier may find that after a few minutes rifle drill becomes impossible or the schoolmaster that after writing on the blackboard for a short time he is no longer able to support the weight of his arm Women may complain that they cannot keep their arms up long enough to do their hair Whatever the initial presenting symptom may be the extent of the disorder gradually spreads until a wide range of voluntary movements is affected

Few diseases present a more characteristic picture than does myasthenia gravis in its established stage The variable and usually asymmetric ptosis is seldom absent It can readily be brought on or increased by asking the patient to look upwards for a few seconds and when severe one or both eyes may be fully closed Unlike the ptosis of tabes there is little compensatory wrinkling of the forehead because the frontales share the weakness of the levatores palpebrarum The ocular palsies are characteristic any or all of the external ocular muscles may be involved and strabismus is common The paralyses rapidly increase in severity and extent with ocular movement and a few attempts to glance from side to side may bring all oculomotor activity to an end The pupils are always normal in their reactions The ocular more than any other muscles show a tendency to develop complete and unvarying *paralysis in long standing* cases and *with the exception of the extremely rare disorder* described as progressive nuclear ophthalmoplegia there is no disease other than myasthenia which gives rise to a complete external ophthalmoplegia with normal pupils in the absence of other signs of nervous disease Fortunately when the stage of permanent ophthalmoplegia is reached the optic axes are usually parallel and diplopia disappears

The facies of myasthenia with its lack of expression the inability to close or pucker the eyes or to wrinkle the forehead and the peculiar weak nasal smile is unmistakable Weakness of the muscles of palate pharynx and larynx may be general or localised and at first is present only after use Permanent paralysis of the soft palate is commonly seen in chronic cases that of the vocal cords or pharynx being much more rare Severe weakness of the tongue may be associated with some reduction in the size of the organ but with this rare exception wasting is not seen in myasthenic muscles nor are the tendon reflexes disturbed Sensibility and sphincter functions are unimpaired The excessive tendency to fatigue which is responsible for the symptoms of myasthenia is also seen in the muscles in their response to electrical stimulation With an interrupted faradic current the contraction of the muscles is at first normal but instead of remaining at a similar strength for an indefinite period it rapidly decreases until it disappears altogether If the stimulation is discontinued for a few minutes and then recommenced there is a further response which tires more readily than the first After exhaustion by faradism some volitional response remains

Diagnosis —This is seldom a matter of difficulty if the variable paralysis increasing with fatigue and improving with rest is conspicuous for this phenomenon

are equally affected Nothing is known of any causal factor, either immediate or *remote*, though the first onset of symptoms has not infrequently been noted after an acute infection particularly of the naso pharynx The one clinical association which cannot be ignored is with exophthalmic goitre for not only may myasthenia follow that disorder but the ocular palsies and muscular weakness which may occur in Graves' disease bear no small resemblance to those of myasthenia

Pathology—The only change found within the nervous system either central or peripheral is slight atrophy of those nerve cells which supply long paralysed muscles and these changes are certainly not primary Nor is there any essential histological change in the affected muscles except where long standing complete paralysis is associated with the degeneration of long disuse Small aggregations of lymphocytes, known as lymphorrhages have been described in the muscles in some cases

In a large proportion of the cases subjected to autopsy some degree of persistent thymus has been found This may vary between a well formed organ weighing several grammes and small remnants or thymic rests These thymic elements may show evidence of proliferation or degeneration

Chemical examination reveals no significant disturbance in the metabolism of glucose calcium phosphorus or creatinine although in common with most muscular disorders, creatinuria may be present in myasthenia There is evidence that the muscle potassium is increased and that it reverts to normal when the myasthenic symptoms are abolished by an injection of neostigmine

The view expressed in earlier editions of this book that the seat of the disorder of function responsible for myasthenia gravis is at the myo neural junction has of recent years received confirmation from observations made with physostigmine and the synthetic substance neostigmine (Prostigmin) It is believed that the normal transmission of impulses from the motor nerve fibres to the voluntary muscles through the motor nerve endings depends upon the liberation at the end plate of acetyl choline In myasthenia the failure of effective innervation may be due to the inadequate liberation of acetyl choline or to its premature or excessive destruction by choline esterase or to the presence of a curare like substance antagonistic in its action to acetyl choline The administration of physostigmine temporarily delays the destruction of acetyl choline by the choline esterase normally present in the blood and during the period of its activity renders muscular contraction normal The exact nature of the defect still awaits elucidation

Symptoms—The onset of the disorder is usually insidious but in rare cases may be acute The symptoms can all be related to excessive fatiguability of muscles and thus make their appearance after use and improve with rest and are most severe in the evening and least marked on first waking in the morning The muscles first affected are usually those innervated by the cranial nerves particularly the external ocular muscles but as the disease progresses the extent of the disorder spreads to involve the muscles of the neck limbs and trunk Sometimes however the characteristic weakness is universal from its commencement

Ocular symptoms are of the greatest importance The clerk finds that towards the end of the day he is seeing double or that one or both upper eyelids droop In the morning on waking the ptosis and diplopia have both disappeared only to return after another day's work The school teacher notices that as he lectures his voice gradually grows weaker and more husky and acquires a nasal quality This too clears up with a rest and is invariably worse towards the end of the day Difficulty in swallowing is a common symptom At the commencement of a meal all may be well but as it goes on the food is forced down with increasing difficulty until finally swallowing is no longer possible Many patients find that they can eat their solid meals only in the early part of the day and by evening can at best sip fluids Nasal regurgitation of fluids towards the end of the day is common. The act of chewing

may give rise to so much fatigue of the masticatory muscles that only soft foods can be taken and towards the end of a meal the lower jaw may be too heavy for the exhausted muscles to sustain and the patient may be seen supporting it with the hand and attempting in this way to supplement the process of mastication The muscles of the face commonly share the weakness Friends observe that towards the end of the day the patient s face is expressionless or comment on the peculiar snarling quality of the smile The patient may complain that he cannot smoke a cigarette or whistle as the lips cannot maintain a sustained pressure In severe cases the eyelids can only be closed with difficulty and it may be noticed that the patient sleeps with the eyes open Fatigue of the neck muscles may be an early symptom The head feels more and more heavy and finally can only be supported with the aid of the hand The weakness may affect any or all of the muscles of the limbs and trunk though the arms are more frequently involved than the legs The soldier may find that after a few minutes rifle drill becomes impossible or the schoolmaster that after writing on the blackboard for a short time he is no longer able to support the weight of his arm Women may complain that they cannot keep their arms up long enough to do their hair Whatever the initial presenting symptom may be the extent of the disorder gradually spreads until a wide range of voluntary movements is affected

Few diseases present a more characteristic picture than does myasthenia gravis in its established stage The variable and usually asymmetric ptosis is seldom absent It can readily be brought on or increased by asking the patient to look upwards for a few seconds and when severe one or both eyes may be fully closed Unlike the ptosis of tabes there is little compensatory wrinkling of the forehead because the frontales share the weakness of the levatores palpebrarum The ocular palsies are characteristic any or all of the external ocular muscles may be involved and strabismus is common The paralyses rapidly increase in severity and extent with ocular movement and a few attempts to glance from side to side may bring all oculomotor activity to an end The pupils are always normal in their reactions The ocular more than any other muscles show a tendency to develop complete and unvarying paralysis in long standing cases and with the exception of the extremely rare disorder described as progressive nuclear ophthalmoplegia there is no disease other than myasthenia which gives rise to a complete external ophthalmoplegia with normal pupils in the absence of other signs of nervous disease Fortunately when the stage of permanent ophthalmoplegia is reached the optic axes are usually parallel and diplopia disappears

The facies of myasthenia with its lack of expression the inability to close or pucker the eyes or to wrinkle the forehead and the peculiar weak nasal smile is unmistakable Weakness of the muscles of palate pharynx and larynx may be general or localised and at first is present only after use Permanent paralysis of the soft palate is commonly seen in chronic cases that of the vocal cords or pharynx being much more rare Severe weakness of the tongue may be associated with some reduction in the size of the organ but with this rare exception wasting is not seen in myasthenic muscles nor are the tendon reflexes disturbed Sensibility and sphincter functions are unimpaired The excessive tendency to fatigue which is responsible for the symptoms of myasthenia is also seen in the muscles in their response to electrical stimulation With an interrupted faradic current the contraction of the muscles is at first normal but instead of remaining at a similar strength for an indefinite period it rapidly decreases until it disappears altogether If the stimulation is discontinued for a few minutes and then recommenced there is a further response which tires more readily than the first After exhaustion by faradism some volitional response remains

Diagnosis —This is seldom a matter of difficulty if the variable paralysis increasing with fatigue and improving with rest is conspicuous for this phenomenon

occurs in no other disease Even so, in its early stages, the malady is often mistaken for a hysterical disturbance More legitimate difficulty may arise when only isolated and permanent paralysis is present, especially as such cases are liable to present themselves in ophthalmic or laryngological departments It should be remembered that any unilateral or bilateral palsy of muscles supplied by the cranial nerves may be myasthenic Here the history of slow onset with variable paralysis and fatigue phenomena, can nearly always be obtained and the absence of the usual signs of gross lesions of the brain stem nuclei or of progressive diseases affecting the latter, should avoid confusion When as sometimes happens, myasthenia begins with a unilateral ophthalmoplegia or laryngoplegia the diagnosis may be really difficult. The possibility of such should be borne in mind and a careful watch kept for the appearance of conclusive evidence An intramuscular injection of 1 ml of the standard solution of neostigmine may be used as a diagnostic test, its effect being to bring about within half an hour the temporary abolition or very great amelioration of any variable symptoms that are due to myasthenia gravis

Course and Prognosis—Although myasthenia gravis is invariably a dangerous disease as its name implies its course is extremely variable In some cases the degree of the muscular involvement steadily increases in extent and severity until a fatal outcome is reached in a few months or years In such cases death usually results from progressive respiratory failure or from aspiration broncho pneumonia consequent upon pharyngeal and laryngeal palsy supervening upon a state of inanition Not infrequently death is sudden and unexpected and appears to be due to syncope In other cases the disorder may remain confined for a long period to small groups of muscles particularly those of the eyes and may result in a condition of multiple cranial nerve palsies of an unvarying character with a survival period of 20 to 30 years In such cases more generalised and active symptoms may reassert themselves at any time and death may occur after many years of stability In yet a third group long periods of complete remission may occur ultimately followed by a recurrence of characteristic symptoms, which on this occasion may prove to be progressive

Treatment—The treatment of this disorder was revolutionised by the discovery of the specific effect of physostigmine and its synthetic relative neostigmine Few things in medicine are more dramatic than the sudden amelioration of symptoms the relief of ptosis the recovery of ocular movement and the return of facial expression that follows the administration of one of these drugs The effect is however, transitory lasting only from 4 to 6 hours and is in no sense curative It is usual to administer 2 to 4 ml of neostigmine (1 to 2 mg) subcutaneously two or three times daily half an hour before meals If the drug causes abdominal discomfort or palpitation it may be combined with atropine sulphate gr $\frac{1}{150}$ Alternatively the drug may be given by mouth in doses of 10 to 25 mg three or four times daily In severe cases the period during which the effect of the drug is wearing off may be attended by severe and alarming weakness and over a prolonged period the beneficial action of the drug tends to lessen and an increased dose is required to be effective The administration of ephedrine gr $\frac{1}{4}$ to 1 b d has been found beneficial it may be sufficient of itself to keep a mild case in reasonable comfort or it may be used as an adjunct to neostigmine

The frequent association of a persistent thymus with myasthenia has long received attention and has led to attempts to treat the disorder by influencing this organ Numerous isolated examples of improvement in symptoms following radiotherapy to the thymus are recorded in the literature but the results were not constant Of recent years a number of cases have been treated by surgical removal of the thymic remnants with encouraging results This operation is one which carries a considerable mortality and should only be attempted by an expert in thoracic surgery Of the patients who have been so treated some have shown a degree of improvement amounting to a cure and quite different from anything seen with neostigmine therapy

Others after a period of improvement have relapsed Others again have shown no material alteration in their condition The procedure should at present be regarded as an encouraging but not yet fully established advance in treatment

FAMILIAL PERIODIC PARALYSIS

Definition —A flaccid paralysis affecting the muscles of the trunk and of the extremities associated with loss of the deep reflexes and diminution or loss of faradic *excitability in the muscles The paralysis is temporary in character though it may* be fatal during the attack and it recurs at intervals It is a rare malady, some 200 cases having been reported in the literature

Ætiology —It has been noted as early as the fifth year and as late as the thirtieth year but usually it appears about the age of puberty Most of the cases occur in the male sex Heredity is very marked and the malady has been traced through five generations Transmission may occur either through the male or through the female and not infrequently a generation is skipped Several members of the same family are usually affected

Pathology —*Several cases have come to necropsy but no lesion which could be* associated with the symptoms was found Biopsy of the muscles has given entirely negative results During an attack significant fall in the serum potassium has been demonstrated An attack may be brought on by a large intake of glucose especially if an injection of insulin is given at the same time

Symptoms —The clinical picture is so striking as to be almost dramatic The patient retires to bed feeling perfectly well and awakens in the morning without pain or malaise but with a flaccid motor paralysis which always involves all four extremities and which may reach all the muscles of the body except those of the organs of speech deglutition and respiration and even these are often partially in volved Severe involvement of these vital muscles during an attack has caused death The bladder and rectal functions are retained and it is unusual for the patient either to void urine or fæces during the attack The paralysis is usually at its height on waking but it may subsequently increase After lasting for a variable time from a few hours to a few days it passes off sometimes gradually sometimes rapidly In one family it was astonishing how the patients on waking in an attack could judge invariably how long the particular attack would last They could judge with unfailing certainty when ability would return and were in the habit of arranging their business accordingly Most of the patients in addition to the severe attacks of paralysis suffer from what they call morning weakness temporary inability to grip with the hands and slight disability with the feet on waking The paralysis in periodic paralysis is flaccid and there is loss or marked diminution of response to faradism during the paralysis The deep and superficial reflexes are lost in the paralysed region Objective sensation is not affected but there may be subjective sensations of tingling and numbness and the muscles may be a little sore and stiff after the attack Flushing of the face and profuse sweating may occur during an attack There is an invariable tendency for the attacks to diminish in frequency and severity after middle life is reached

Diagnosis —This must be evident to any one acquainted with the symptoms of the disease

Treatment —Potassium chloride in large doses (up to gr 30 or 40) will avert or cut short an attack No other remedial measure is known

SECTION XIX

PSYCHOLOGICAL MEDICINE

INTRODUCTION

Psychiatry is concerned with forms of illness as widespread and diverse as those of somatic medicine There are almost as many beds in mental hospitals colonies for defectives and allied institutions as in all other hospitals put together and there is an undoubtedly large, if unnumbered part of the population who have mild mental disorder not needing mental hospital care hysteria obsessional neurosis hypo chondria chronic depression paranoid states and so forth The diversity of this widespread group of illnesses depends on their being disorders of mind—disorders that is, of the human function which comprehends and sums up all other functions of the organism serves to relate a human being to his complex environment and is the chief token that he is an individual, and not a sample Mental disorders are therefore varied as are the people who suffer from them It is only by ignoring most of what is individual in these illnesses that a few common types or categories can be recognised, comparable to the diseases of somatic medicine Such a procedure is necessary for practical ends material must be classified Moreover a biological foundation may be assumed for the syndromes with which psychiatry works They stand for the main ways in which a human being can become mentally unhealthy There are only a few such ways and they are determined by the struc tural and functional patterns inherent in the organism Diversity arises through their becoming manifest under the influence of each individual s special environment and in combination with his other inherited tendencies Diversity therefore can be due to a combination of single hereditary causes and to the effect of each individual s environment throughout his life upon his development and behaviour There is always interplay between inheritance and environment Part of the psychiatrist s business is to discover how this interplay has led to the present illness The inter play moreover is sufficiently varied in the course of each patient s life to make prog nosis and the effect of treatment a matter of individual study rather than of summary inference from the diagnosis once made

Treatment is only another special instance of the environment acting on the patient its power and limitations for him cannot be judged without considering what effects this or that experience has had on his previous life Consequently the psychiatrist even more than the general physician must study illness in two ways first as showing some typical pattern of morbid behaviour with characteristic patho logical changes and tending to run along well known lines and secondly as a patch of personal biography something to be understood rather than classified in terms of psychology and physiology The two methods are complementary though in a brief textbook presentation the former must be the more prominent

There is no dividing line between somatic medicine and psychiatry Psychiatry although it has to work in part with social and psychological conceptions of which general medicine has hitherto felt less need suffers greatly when it limits itself to this way of regarding mental phenomena It cannot safely ignore the relationship between bodily happenings and the patient s state of mind Crude instances of this relationship are the delirium that accompanies an acute fever and the irritable fatigue (neurasthenia) that may follow it the insanity that is due to cerebral tumour or general paralysis of the insane the obsessional neurosis that follows encephalitis lethargica and the hysterical symptoms of disseminated sclerosis There is no

mental disorder, mild or severe, in the causation of which bodily disease may not play an important part Moreover it is not only in crude instances of structural or chemical disease that the relationship between bodily and mental illness may be recognised A human being does not exist as a rarefied mind united with a solid body he is an organism all of whose subsidiary functions contribute to this highest function—his mind—which brings him not only consciousness but also an integrated behaviour in relation to his surroundings Disturbances transient or permanent, of these part functions (for example in the sensory apparatus or the circulatory system) will have some effect on his state of mind Changes in the central nervous system are the most obvious instance of this but the endocrine glands the autonomic nervous system and the metabolic processes are often of notable significance in the various maladjustments summed up as mental disorder A human being is constantly responding to and influencing his surroundings but his doing so is conditioned by the various parts of his body and the way they are working It is likewise and equally necessary to weigh psychological influences and effects when deciding the pathogenesis or the treatment of predominantly physical illness The part that emotion may play in the chain of events that cause or aggravate peptic ulcer has been lately demonstrated in a manner to convince the sceptic and there is less dramatic but equally weighty evidence attesting the interplay between psychological and physical happenings which may influence the outcome of many a surgical or other illness Much of the recent enthusiasm for psychosomatic medicine turns on a belated recognition of this It is plain that psychiatric issues must be the concern of all doctors not merely the psychiatrist s preserve and that psychological happenings differ from physiological in their deceptive accessibility to familiar methods of observation in their almost Gordian complexity and in the concepts found most useful for describing and explaining them rather than in any essential quality which would keep them permanently distinct

Before the categories and clinical features of mental illness are described the principles of psychopathology prognosis and treatment call for some very brief consideration since without them psychological medicine written down is a repellent catalogue of details Though the principles set forth may seem trite or too obvious to be worth stating it is unfortunately the case that they are often not applied as fully as they might be to the clinical study and treatment of mental disorders

Psychopathology —INTRINSIC CAUSES —The intrinsic causes of mental disorder are those which depend on heredity and on phases of development *e g* the climacteric Extrinsic causes which come from the environment are either mental experiences or physical damage The distinction between intrinsic and environmental like that between physical and mental is convenient but artificial a long sequence of related happenings both within and without the patient s body goes to the causation of any mental illness It is of course possible in many instances to discover some indispensable link in this chain of causes—an intoxication with alcohol for example a syphilitic infection of the brain an inherited predisposition to periodic insanity a bereavement—which may legitimately be singled out as the chief cause and classified as intrinsic or extrinsic but this is more valuable for formal and didactic purposes than clinically Actual cases usually show a complicated ætiology Thus a man whose parents had both been subject to melancholia became himself profoundly depressed after the death of his wife and attempted suicide by drowning He survived but during the resulting pneumonia he was delirious and threw himself from an upper window crying out that he must go to his wife The causes of the mental disturbance in this case were many and obvious numerous they always are but not always obvious One cause may of course be prepotent

The more detailed the analysis of a patient s endowment and experiences the more entangled physical and psychological internal and external factors seem to be

Heredity and constitution —The hereditary factor is not a general neuropathic

taint there are specific predispositions to one or other anomaly These predispositions are transmitted in accordance with familiar genetic principles summed up in the modern gene theory of inheritance Studies of families and of twins have proved the importance of the hereditary factor in the major non organic psychoses though they have not yet sufficed to reveal with certainty the number and location of genes concerned in the transmission of the hereditary types of morbid reaction

Among the main reasons for this incompleteness in our knowledge is the impossibility of concluding that an inherited trait is not present, merely because it is not manifest in some recognisable form Other inherited factors and most of all the environment will in many cases determine whether an individual predisposition is to become evident or not Thus a man may have an inherited tendency to melancholia which remains latent until a financial reverse or disease of the cerebral arteries provides the conditions necessary for its manifestation It is true that some inherited predispositions e g to Huntington s chorea are almost independent of the environment in this respect but such are exceptional

More than one type of proneness to mental disorder can be inherited by the same person He may for example be prone not only to periodic insanity but also to schizophrenia Mingled proclivities of this kind account for anomalous clinical pictures frequently met with and difficult to classify as either one syndrome or another The ' either or kind of diagnosis is often out of place or misleading in psychiatry because of the commonness with which more than one constitutionally rooted type of illness may be found in the same patient Syndromes are frequently combined, to grasp their clinical meaning one may have to investigate the patient s family not only as to mental disorder, but as to normal characteristics of temperament also

The signs of a transmissible tendency to some mental disorder may not be actual illness but only a special kind of personality There are certain varieties of personality which show some of the essential features that characterise certain types of mental illness, the differences between personality and illness seem then to be of degree rather than of kind Moreover those who manifest one or other type of illness are often found to have had the type of personality that is functionally similar to it So close may the similarity be that it is difficult to decide when the illness has begun because there was no sharp dividing line in time or in form between the more or less normal previous personality and the actual disorder This frequency of association and similarity of form between the normal state and the illness points to the constitutional background of mental illness and shows how hereditary tendencies can express themselves in more or less normal ways in personality before the catastrophe of an obvious illness has directed attention to them Nor is it only in the personality that inherent proclivities may be revealed certain types of bodily structure too occur much more frequently in those with a particular mental constitution or mental illness than in the rest of the population The most striking instance of this is the frequency with which a pyknic bodily habit and a syntonic personality are found among those who have periodic attacks of mania or melancholia (see p 1646) It is not common to find pure examples of mental or physical types in the population and recent work e g that of Sheldon has aimed at making it possible to designate the mixture of components in any individual by a taxonomic formula rather than by ascribing them all to one or other type but whatever method of description be employed the association of osseous and muscular structure with a particular personality structure and perhaps with a predominant form of autonomic response seems frequent enough in healthy as well as mentally ill persons to warrant classing physique physiological behaviour and personality together however tentatively Such constitutional features whether mental or physical indicate that inherited tendencies can body themselves forth in normal physical and psychological structure before morbid exaggerations of them make an appearance The varieties are some-

times called by appropriate names e g schizoid cyclothymic syntonic obsessional hysterical paranoid The relationship is not a simple one There are very many people with these types of personality who never fall mentally ill

A pronounced personality, belonging to one or other of these types does not indicate that the person who exhibits it is likely to have a mental illness but only that if he should have a mental illness it will probably be of the corresponding type As with all inherited anomalies of which the crude manifestation is delayed until adult life there may be for many years none or only mitigated signs of the proclivity these may be indistinguishable from what occurs in normal people The more pronounced the anomaly of personality the more likely that it portends a mental illness, or at any rate a proclivity to the mental illness in specially adverse circumstances

In studying personality, the psychiatrist can have recourse to several techniques besides direct observation and the descriptive method based on the reports of those familiar with the individual studied The most ambitious are projective methods of which the Rorschach ink blot and the thematic apperception test are examples The patient s fantasy is evoked by more or less standardised stimuli and inferences drawn from what he says and does in these circumstances Expert and cautious interpretation is indispensable This applies to the whole of the growing array of psychological methods of assessing personality

In the foregoing personality and constitution have been spoken of as though they were static, innate attributes of the human organism Neither of these epithets however is appropriate not even in respect of bodily constitution Responsiveness and plasticity are essential to human development of every kind there is a constant interplay of personality with the outer world modification of it and by it The main pattern of development is doubtless determined by innate inherited factors—bodily structures grow instincts come into play and the general direction of functional activity is predetermined But general directions and main patterns mean little unless they are given body and content by individual experience Nutrition for example can deflect the body from its ordained pattern or enable its fulfilment all sorts of physical interference can maim it or improve it the same is profoundly if obviously true of the mental side of human growth and maturity Consequently each patient s personality is not to be assessed as conforming to a frozen artificial type but as a complex of dynamic functions changing in outward form sometimes in unstable equilibrium and none the less powerful for being subterranean Here as was said earlier of psychiatry in general there must be two ways of viewing the data in classes and as individual living biographies to be understood rather than schematised Both methods are necessary to any complete psychopathology

Phases of development —A concrete instance of the foregoing is the change that occurs at certain turning points such as puberty pregnancy or the climacteric Endocrine and other physical changes at these epochs may be accompanied by psychological disturbances the severity and form of which bring them under the notice of the psychiatrist They are dramatic episodes in a lifelong process of growth maturity and involution or decay which is marked by plasticity and development of varied functions in the first stage stability and differentiated adaptation in the second emotional lability and suspicion intellectual narrowing rigidity failing grasp and memory in the last The mental disturbances which may occur at different ages are much influenced by these intrinsic factors and tendencies

EXTRINSIC CAUSES —The outer world impinges on human beings from the day of their birth or even their conception in more and more complicated ways as they themselves become more complicated In other words the environment is for the individual as complicated as he can make it and that will depend on how far he has himself developed hitherto Human beings deal selectively not merely passively, with experience At each stage of their growth previous experience helps to determine what they will select from their environment and how they will use this and

integrate it, to serve in its turn as the partial determinant of further growth and integration (the other determinants being innate ones) Experience ' is here being used in the widest sense to denote the response of a human being to the impact of the outer world upon him, whether it be consciously recognised as such or not at the time

It is therefore, impossible to give adequate consideration to any aspect, including the psychological of a human being s way of dealing with the outer world unless one pays regard to his previous experience mental and physical and to the present state of his whole organism mental and physical The cultural milieu in which he has grown up must be taken into account *Too partial a regard for subsidiary functions* whether physiological or psychological may lead one away from the living human being who is an integrated organism not a collection of disparate mental and physical systems similarly *too concentrated a gaze on this latter aspect i e on the socially* organised person to the neglect of part functions may make one see only a dis embodied spirit, as remote from medicine as from daily life

Physical experiences —Some external happenings influence the mental state chiefly by way of the body infection physical trauma intoxication and metabolic and endo crine disturbances due wholly or in part to environmental influences may result in mental disorder In many of these instances the mental change is mediated by way of some cerebral damage and the clinical picture is of the organic neurogenic kind *e g* dementia It would be wrong to attribute the whole of the mental disorder to the cerebral damage, but to it is referable the core of the psychosis Some diseases have an incidence on special functions and parts of the central nervous system which determines characteristic features in the mental picture *e g* the anxious fidgetiness of the patient who has had chorea the stiff mind and obsessional thoughts and move ments of the post encephalitic the hysterical phenomena of the elderly arterio sclerotic patient or the man poisoned with carbon monoxide the aphasia and apraxia of the post apoplectic, the silly moria of the cerebral tumour In the main however it is not possible to correlate mental symptoms with special areas or kinds of cerebral damage—partly because the brain is not the only structure concerned partly because it acts as a whole and also because the presumptive changes in it are too evanescent and delicate to be accessible to our crude methods of examination Even the electro encephalogram which seemed to promise so much has contributed little to the understanding of cerebral happenings in mental disorder other than epilepsy though it is valuable in suggesting the presence or indicating the site of a lesion *e g* in the temporal region

To limit oneself to the brain in studying the somatic correlates or basis of mental phenomena would be an error In the physical accompaniments of emotion the whole body participates through the mediation of the vegetative nervous system and the endocrine glands This is significant because emotional upset is one of the most important phenomena of mental disorder The sequence of psycho physical happenings of which an emotional upset is the climax and the outward sign may be started not only by some mental happening but also by physical experiences—intoxication with a drug or a circulatory disturbance or a metabolic upheaval such as acute hypoglycæmia Whether for example this hypoglycæmia comes from out side as an injection of insulin or arises (as it rarely may) from within the body as a spontaneous deficiency is of little consequence in its bearing on the mental disturbance engendered The chief emphasis lies on the physical apparatus through which so widespread an affection of the whole organism can be evoked just as in other circumstances the emphasis would lie on the psychical apparatus which serves the same end This applies more widely than to emotional disturbances alone Where a symptom is on the face of it *definitely physical or definitely mental* its causation may not be inferred to be exclusively of the same order the chief cause of say an anorexia may be a series of mental experiences or an attack of migraine or

a uræmia or a pituitary disease Study of the anorexia alone cannot serve to discriminate them not even study of the psychological state alone or of the physical state alone may suffice Very often the physical and psychological factors in causation are mingled inextricably—they represent of course different facets of the same series of phenomena

Mental experiences —Mental growth is dependent on daily experience for its material Experience can be subdivided into perceptual emotional and other kinds but such a division is fictitious The means by which daily experience is incorporated with our mental equipment and acquires an influence over our subsequent behaviour in all respects can only be understood if we avoid thinking of emotions instincts perceptions and other abstractions as real entities as distinct and separately operative forces Memory for example is not merely an intellectual function by which we recall a happening into consciousness in more or less verbal terms but a device or function by which past happenings are able to influence subsequent behaviour the ways in which they do so and the form in which the earlier experience is reproduced into consciousness will be greatly influenced by its original emotional as well as more purely perceptual aspects and by other physical and mental experiences—a distressing repetition of the experience for example or a physical happening like concussion or cortical atrophy

There are general needs in mental life—instinctual needs—which bring us into relation with our immediate surroundings lead us to feed ourselves maintain our lives reproduce and aim at other ends which have been variously formulated by philosophers saints and psychologists These biological forces however denominated or classified are not peculiar to human beings but in respect of human beings are so much more accessible to minute enquiry along verbal lines that complex conceptual systems have been built up to describe them Comparative and experimental psychology have partly corrected unreal refinements and highly metaphorical interpretations physiology can also help here Unduly speculative subtleties *e g* some psychoanalytical ones are ill suited to medical needs The influence of previous experience on all subsequent behaviour is as evident in physiological happenings as in the mental field the special language and formulations and hypotheses of psychology are not to be taken as permanently di tinct from those suitable to less highly integrated functions though much must be conceded to the special complexity and character of psychological phenomena Such terms as projection sublimation conversion symbolism identification repression amnesia perseveration displacement of affect cover special instances of the general relationship between inherent tendencies of the organism and their material substrate and the influence of past on present experience and behaviour

In dealing with the multifarious world about him a human being is constantly obliged to select what he will perceive and in what form he will perceive it pure objective perception never occurs To perceive things at all he must give them meaning by relating them to himself and to his previous experience Unless he can do this not necessarily consciously he is at the mercy of his environment as a new born baby is Perception is therefore an active process it has instinctual and emotional as well as cognitive aspects It depends partly upon memory for being able to give meaning to what it perceives such memory need not be conscious Consciousness it is well to bear in mind is only an attribute of psychological happenings not their essence or their criterion mental life goes on with varying degrees of consciousness attaching to it There is no sharp division between conscious and unconscious mental life no region called the Unconscious with its own rules and contents Many of the psychological happenings most significant for psychiatry go on without clear consciousness of them but in appropriate conditions they may be accompanied by much more or by full consciousness Biologically and psychologically regarded consciousness is an attribute like movement or the ability to learn

immensely important for us human beings, but not a 'present or absent factor decisive for our mode of mental conduct

Perception being thus an active process which makes use of past experience it not only selects its material and invests it with meaning but in doing so may distort it and give it a special false meaning Unwelcome emotions may be thus projected on to external objects or happenings, which are then regarded as hostile or contemptuous or in some other way significantly related to one s self This is not remote from the process in visual perception whereby one projects the image on one s retina into the external world and is convinced of its reality there, the further process of clothing it with emotional significance depends on one s inherent tendencies and one s previous experiences Paranoid symptoms ideas of reference, grandiose and *self reproachful delusions exemplify this* Hallucinations and kindred phenomena are a special instance of the interplay between material substrate (*e g* in cocaine poisoning) inherent tendencies (*e g* visual fantasies of children) and past experience (*e g* hallucinations *of homosexual abuse or divine commands*) *Similarly* by fantasy and imagination the outer world can be manipulated or denied according to the heart s desire just as by body images of proposed movement the way is prepared for purposive muscular action In giving meaning to present things personal connections between them and earlier experiences are established, whether normal or morbid this ascription of symbolic' meaning to everyday objects is indispensable to thought, and is most striking in our use of spoken or written language, where sounds and shapes are conventional symbols for the most diverse experiences Some of our words are personal to ourselves and are used in an individual way, in morbidly heightened form this process may issue in schizophrenic neologisms or oddities of expression *Similarly* an obsessional patient may feel towards some word *or object* a superficially incomprehensible mixture of attraction and repulsion which is due to this word or object being the symbol of some earlier experiences that have been of great moment in his life To see how it has come to be such a symbol calls for minute study of his earlier experiences Physical happenings in one s own body may symbolise present emotions or earlier experience of a momentous and emotionally painful kind A gesture of disgust may normally be evoked unconsciously by a banal happening which has somehow become emotionally coloured by past experience A headache or nausea may embody our dissatisfaction with a present situation So hysterical " conversion ' symptoms may reflect and symbolise an inner emotional struggle as may also some obsessional movement schizophrenic stereotypy or *hypochondriacal* fear The body with all its functions is the background of psychic life and resonates to it

What experiences will be important in determining the form of mental symptoms depends much on the emotional disturbance they originally provoke and this in turn on the instinctual drives which they touch on and disturb Instinctual needs may conflict, and the emotion accompanying the conflict prove so disturbing that it cannot be borne in its naked form repression serves the end of making this more or less tolerable through disguising or distributing it So emotion may be shifted from one object to another and paradoxical or unexpected emotions be thus aroused by objects on to which the affect has been *displaced* *Or energy* mainly directed to plain ends *e g* sexual love may be diverted into less obvious channels and when thus sublimated and mingled with features derived from other instinctual sources *its origins* may be hard to recognise Sexual needs so often conflict with others that many of the most powerful motives for the production of mental symptoms come from the struggle

To describe the whole of instinctual life however in terms of sex and aggression as has sometimes been done is only possible if one strains *the meaning of* these words out of all knowledge It is as unwise to make the sexual paramount in psychogenesis as to burke it.

The patient s present symptoms it is clear must be examined in the light of his earlier experience Thus one elucidates in detail the content of his illness and some of the causes of its occurrence In doing so it is not necessary to push back all one s enquiries to a supposedly crucial stage of early childhood The experiences of the first 2 or 3 years of life are like all subsequent experience contributory to mental development and they show certain sequences of phenomena characteristic of such development Moreover their relative simplicity makes it possible to recognise in these early reactions the instinctual drives or (more correctly) the inherited functions which become manifest when the environment supplies the necessary material, though of course it cannot supply the necessary energy and direction these last must come from within On the other hand the functions recognisable in the relatively simple reactions of early childhood are not the same as those which may be seen in later years when the organism is more fully grown any more than an infant s physical structure and functions are identical with those of the more differentiated adult The obvious continuity of the actual happenings in a human being s lifetime does not justify one in trying to analyse and reduce all adult mental phenomena into terms of child psychology nor does clinical practice usually require it

The effect of war and famine upon the incidence of mental illness has obvious importance The psychiatric disorders which occur in war do not differ in kind from those of more normal times but certain forms of disorder especially panic exhaustion psychogenic semi stupor and gross hysteria in men, become commoner and sometimes more severe People are exposed to unaccustomed dangers their privations are both material and emotional they have to surrender some of their independence and individuality and they are thrown together in groups and therefore prone to share in group feelings and group behaviour It is not known whether the losses fears misery and other psychological burdens and cruelties of modern war and its aftermath directly lead to an increase in certifiable mental illness though such exogenous factors as malnutrition and infectious disease which war favours may have this effect It is however neurotic disorders that chiefly excite attention during war as they are then more certain to be ascertained they interfere with military efficiency they can impair morale and a far higher proportion of affected people come under medical scrutiny than is customary during peace

Course and Prognosis —The making of a correct diagnosis may in psychiatry indicate the general drift of an illness—towards recovery chronicity progression or relapse—but is of even less use than in the rest of medicine for showing how far this will apply to a particular patient For this careful study of the individual history and illness are indispensable The prognosis can be inferred from the causes the mode of development and the form of the disorder

Where a known external cause has been at work its point of attack its severity and persistence will affect the issue This applies equally to such organic causes as poisons and cerebral diseases and to mental causes like economic misery or frustrated love The physician must consider how long the environmental cause has been acting what changes it is known to produce—cell degeneration or gloom fibrosis or fantasy—and whether it is likely to persist He must also ask if the patient s previous history has shown that he is specially sensitive to such a trauma This brings in the intrinsic causes How has the patient previously reacted to this sort of interference or to any disturbing circumstances ? Has he fallen more and more into unsatisfactory habits in meeting his daily life and its difficulties ? How has his whole character developed ? Is there good evidence of his being able to cope with partial deviations from mental health ? Has he inherited tendencies to benign or to progressive illness ? Which seem to be the most useful reparative or stabilising features in his personality ? How far are his struggles with the world an outcome of his intrinsic endowment evident in various guises since his childhood how far have they been forced upon him by an adverse milieu ? How old is he ? There is

more chance, if he is young of his being adaptable so that the removal of various stresses may help him and his energies be diverted into less morbid channels, as he grows older he may gain in stability but gradually become more disposed to fear and suspicion bodily preoccupations and fixed attitudes of mind

An abrupt onset is favourable other things being equal A gradual especially an insidious onset may indicate a rooted abnormality that will be hard to shift The longer an illness has gone on, the more will it have become autonomous, *i e* independent of the immediate causes of its occurrence A study of the ups and downs in the course of an illness may show favourable influences that can with profit be deliberately brought to bear on it, as well as harmful ones that must be avoided The more reconciled the patient has become to his illness the less likely his recovery

As to the prognostic conclusions that may be drawn from the form of the illness there is much empirical knowledge at our disposal Thus a predominantly affective attack will very likely clear up but may recur a schizophrenic syndrome is ominous in the long run hypochondria and depersonalisation especially in young people tend to last a long time even years sexual perversities can seldom be got rid of altogether hysterical symptoms can easily be changed but hysterical reactions are persistent, obsessional illnesses are either periodic or very chronic melancholia is often a fatal disease through suicide or refusal to eat delirium tremens commonly ends by crisis or lysis after about 7 days untreated general paralysis of the insane goes downhill towards dementia and death with partial remissions on the way and so forth There is a wealth of such special prognostic knowledge based on clinical observation and statistics

Obviously prognosis must always take account of treatment Will treatment be efficacious ? Will it be practicable ? Will the patient accept it and keep on with it ? It would be absurd to forecast how general paralysis will turn out if one did not know whether one would be giving penicillin or how hysteria would turn out before one had decided whether psychological and social treatment would be possible In every mental illness this is one of the essential points to be weighed in prognosis what will be the conditions beneficial neutral and adverse under which the patient is going to live henceforth and in particular, what specially devised conditions social psychological and physical are practicable and likely to have therapeutic effect ?

Treatment —PROPHYLACTIC —Much can be accomplished by social measures also by individual care though that is less certain A striking instance of social influence in preventing mental disorder may be seen in the drastic reduction in alcoholic psychoses Morphine and cocaine addiction and lead encephalopathy are now rare typhoid delirium is exceptional and typhus unknown It is the organic mental disorders that have been more accessible to these preventive methods so far because they have one indispensable cause that can be controlled The functional disorders are partly due it is true to social causes such as rigid or inappropriate moral and cultural standards bad upbringing and ill judged interference Though the total removal of these is far off there is much room for prevention here A preventable social cause may be well seen in compensation neurosis where the administration of a humane statute involving lawyers insurance companies doctors employers and employees often has the inhumane effect of evoking hysterical symptoms anxiety and a depressive or paranoid invalidism in the injured man

Individual preventive measures cover both the intrinsic and the extrinsic causes Eugenic precautions such as birth control or voluntary sterilisation (if legalised) may under skilled guidance prevent some mentally unstable persons from being born to parents who having had mental illness themselves do not wish to propagate it If physical factors *e g* diabetes be prominent in causation it may be possible to prevent the mental illness or at any rate to scotch it in its early beginnings by dealing with the somatic disorder Thus there are fewer cases of syphilitic psychoses now

that syphilis is less often contracted and earlier treated The psychological reactions to a physical disease or blemish may be favourably modified or averted when fore seen It is for obvious reasons impossible to counteract mental disorder by regularly protecting the patient from physical or psychic trauma in any case a life guarded against risks and painful experiences would be almost certain to issue in mental ill health out of its very emptiness By altering a patient s environment and way of living one may however be able to avert an impending illness only study of the individual patient can show how this end may be achieved Making the patient s environment easier for him may be difficult in some instances because doing so would conflict with his obligations toward other people and even if on balance a change of this sort seems essential the patient may thereafter be troubled by guilt and shame This is particularly evident in unsettled times

The work people do and the conditions under which they do it influence their mental health By ensuring that good vocational advice is available to those about to enter the field of employment and to those whose maladjustment is connected with *their occupation useful preventive work can be done*

How far the treatment of behaviour disorders and neurotic traits in childhood can be trusted to avert outbreaks of definite mental illness in later life is a disputable matter but it is fairly certain that by taking advantage of his plasticity and responsive ness a bent can often be given to the energies of the maladjusted child which will result in his being socially better adapted and better able to deal with his problems The more persistent the beneficial influences one can bring to bear on development at this impressionable age the more valuable the prophylactic effort

Many of the most effective and urgent measures of mental hygiene that may be recommended to the community as a whole are still largely of a negative kind what to avoid rather than what to do This applies particularly in the field of sexual prac tice and belief where needless fears and harmful education are rife as with regard to the masturbation of adolescence—a normal and comparatively harmless phase of *sexual development*

TREATMENT OF THE ACTUAL ILLNESS —This is almost as varied as ætiology There are no specific methods of treatment of sure efficacy nor can treatment safely be limited to one approach whether physical psychological or social There is no valid distinction between palliative and curative therapy the distinction should be between more efficacious and less efficacious The nearest approach to a successful causal therapy is attained with those mental disorders which are closely related in time and form of occurrence to some indispensable cause *e g* a toxic delirium a reactive depression or anxiety an interstitial syphilis of the brain But these are rare condi tions if one considers the whole of mental illness The treatment of general paralysis by artificial fever was not causal its theory was dubious its basis quite empirical yet it was the most important therapeutic advance in psychiatry for a hundred years One cannot despise any measure that promotes the recovery or well being of the patient the giving of drugs the prevention of suicide occupational therapy analysis of motives induced convulsions removal into favourable surroundings hypnosis insulin re education and other means of helping the patient are not to be graded in an arbitrary hierarchy nor should recovery be called spontaneous—as it often is— if it has occurred after treatment which did not include psycho analysis or vigorous physical procedures

Sometimes a patient s condition demands energetic intervention sometimes it demands restrained symptomatic treatment sometimes social adjustment is called for sometimes drugs Whether the accent in treatment shall fall on the physical or the psychological or the social side will often be less important than care that all the available resources are used It should not be taken for granted that a diagnosis connotes a method of treatment *e g* that psycho analysis is the only thorough treat ment for obsessions while for depression convulsant therapy is the proper method

Nor to mention another common error, should it be lightly assumed that a heavily tainted family history or other evidence of a strong constitutional factor indicates that treatment is out of the question a superfluous struggle against fate

Treatment may be considered as social, psychological and physical For some types of illness obviously much more stress will fall on one than on another of these *e g* in hysteria general paralysis of the insane epilepsy

Social and occupational treatment —The first task in social treatment is to decide where the patient is to be looked after Is he fit to be at home should he be in a hospital or in some other environment ? The decision as to the need of a psychiatric hospital rests in the first instance on the danger the patient presents to others or the chance of his committing suicide These two problems of behaviour were at one time almost the only grounds of admission to a mental hospital but such questions of certifiability need no longer preoccupy the psychiatrist since voluntary treatment has broadened the scope of the mental hospital and modern conditions made it suitable for many patients who would ordinarily be regarded as "neurotic" rather than mental, psychotic or "insane" (*e g* early cases of general paralysis masquerading as neurasthenia or obsessionals who fear their own impulses and want to be protected against themselves)

The social decisions in treatment cover much more than merely the mental hospital issue If the patient s immediate environment contains many disturbing influences it will be desirable for him to be away from them temporarily at least so long as this does not entail worse troubles summary decisions are here impossible It may be useless to get a woman who is paranoid about her neighbours to move to another district to escape them unless it is the actual conduct of the neighbours and not the patient s morbid attitude that is provoking her suspicion of them It requires a close knowledge of the facts as well as wisdom and psychiatric experience to give advice on matters that may wholly alter the course of a patient s life—advice, say about separating from his wife giving up his job or emigrating to the Dominions Many instances of this might be offered Neurotic patients are often advised to get married especially if loneliness and sexual needs trouble them as though marriage were a panacea such advice by rule of thumb too often makes their condition worse ruins the life of the person they marry and results in offspring that have to be treated at a child guidance clinic Weary depressed patients are often harmfully urged to go to dances and lively seaside resorts where they must try to look happy Hysterical patients do not benefit by being put among people who are hostile and contemptuous any more than in an atmosphere of mawkish sympathy and compliance

In the social treatment of patients indispensable help can be given by trained psychiatric social workers Their assistance is not restricted to the patient s economic problems No psychiatric hospital or clinic whether for outpatients or inpatients children or adults can do its work effectively unless a psychiatric social worker is a member of its staff to provide expert information and advice on all the social aspects of the patient s illness and to carry out social measures of treatment Similarly a non medical psychologist must be available for help in dealing with educational and vocational problems and the administration of specialised tests

Occupational treatment is important for all kinds of mental disorder Where there is acute overt emotional disturbance rest is at first desirable as also for confusional and delirious states In these conditions opportunity for occupation must be gradually offered to the patient as his disorder subsides steady simple work is preferable to the restless unsatisfying fickle activity in which he would often engage if left to himself The less acute any mental disturbance the more necessary is it that occupation should be urged upon the patient and that it should be disciplined and congenial This applies equally to gross psychoses and minor affections of the neurotic sort Allowance must be made for the patient s bent his symptoms and personality and especially his more or less conscious reasons for working and not

working, hence there will be much diversity in the conditions of his occupation whether it be therapeutically contrived in a hospital offered at a Rehabilitation Unit or sought out as remunerative work in the open market Mental health cannot be permanently retained unless one does some satisfying work often it cannot be re covered unless one does Work is not satisfying in the long run if it is done mainly as a diversion to fill in time

Psychological treatment—There is no form of treatment which has not a psycho logical aspect and result The term psychological treatment or its synonym psycho therapy is however conventionally limited to those forms which depend upon direct and personal relationship between the patient and the physician They have been given separate names and divided into schools and techniques Stress may be laid upon the prestige of the physician (as in hypnosis) the patient s attachment to him in all its complicated phases (transference) the trained understanding and thoroughness with which he clears up the patient s problems (persuasion re-education distributive analysis) or on his qualities of personality—enthusiasm energy warmth candour wisdom In so far as psychological treatment is necessarily based on a personal relationship it cannot be made a routine except in its non essentials whatever rules the psychiatrist follows or whatever the training he has undergone he himself is more important than his method in benefiting the patient To that great extent psychotherapy is not a scientific procedure That is not to say that method and training are of no consequence—far from it—but only that they are devices whereby the influence of one human being upon another s mind and conduct can be turned to the best medical ends and the dangers inherent in such a relationship minimised

The more specialised intricate or esoteric the method the less suitable is it to be used by any but the expert It is not proposed here to detail the many kinds of technique that have been employed The general rules that must be followed in any psychotherapy are

1 To regard the removal of symptoms as a good thing but the maintenance of normal social adaptation as far better It is bad to get rid of one symptom only to see it replaced by another but much worse to get rid of all symptoms only to see the patient at the end of treatment a dependent and introspective hypochondriac of the mind a social invalid

2 To seek for the psychological causes of the patient s illness only to the extent that the patient s well being demands which is often far short of what one s own interest and psychological curiosity would demand

3 To consider carefully whether any shock to the patient any aggravation one produces in his illness even temporarily may be a sign of bad treatment

4 To be satisfied with the patient s recovery and not to aim at his promotion to a state of ideal mental health and self understanding It is better that treatment should be quick and effective than drawn out to meet theoretical standards

5 To understand the development of the patient s illness and to interpret it both to him and to oneself in terms of real experience rather than of hypothetical forces

6 To treat the patient without allowing one s own emotions to be more con cerned in the course and outcome of the treatment than is usual in the treatment of a physical illness

7 To aim at harmonising the patient s mental life by giving his ill managed energies fitter material to work at and release from the burdens laid on them by past experience

It is impossible to describe in general terms what the psychotherapist does other-wise than by *metaphor or analogy he promotes the ventilation and desensitisation* of emotional disturbances he elucidates latent or obvious muddles disentangles conflicting tendencies giving them new incentives and a different direction and so

guides the patient through the maze of his life s experience as recalled in memory that he is then better fitted for dealing with current experience knows himself better and has somewhat purged himself of past harms All analytic' methods review the patient s life as he recalls it under special conditions, *e g* of free association hypnosis biographical scheme, etc They stop at different points some aiming at emotional clearance by abreaction some at a redirection and liberation of the instinctual bases of character, while others remain content with an educational achievement

Whether psychotherapy in the above sense is to be applied will depend on the following factors the patient should be willing to co operate in the treatment, free from such hindering disabilities as say deafness able to give the necessary time, of at any rate average intelligence still capable of modification (as he would not be in old age or with very long standing and indurated habits of faulty reaction or with organic cerebral disease) and finally endowed with a considerable residue of normal mental functions with which one may work The more profound his aberrations as in schizophrenia or the more extreme his emotional disturbance as in agitated melancholia the less is he fit for psychological treatment of this individual and specialised kind Psychological treatment however in the literal and larger sense of the words is essential for every variety or stage of mental illness and every degree of co operativeness or intelligence It is a wide notion including all that may ease or reassure the patient bring him to a better relationship to those around him and with himself and protect him from being distressed by the ignorance lack of tact or thoughtlessness of others It is as much negative as positive One must avoid arguing with the patient, telling him lies for his own good or to avoid unpleasant scenes cajoling him making promises that will not be kept threatening or punishing him jesting at his expense losing one s patience with him assuming he is indifferent to what goes on because he looks indifferent provoking him by petty supervision or frequent rebukes, one should not assume that he is quite irresponsible or quite responsible nor talk theory to him nor get on a false footing through ready assent to his delusions and his point of view The physician and the rest of those who are in contact with the patient must do certain positive things make due allowance for his disorder influencing his conduct use their understanding of the psychological happenings without saying so take advantage of every opportunity created by other methods of treatment When occupation narcosis hydrotherapy a course of insulin, massage a physical illness or other happenings bring him more closely into contact with nurses and physicians there are chances of unobtrusive psychological treatment in the wide sense

Of late much effort has been put into treating patients not as individuals but as members of a group Though less economical of time and labour than had been hoped this has the advantage of utilising for therapeutic purposes the influence that patients have on one another Many devices have been employed from social club meetings to psycho drama —plays that originate with the patients and touch on their conflicts and are followed by a group discussion The procedures are still experimental and have not made individual treatment superfluous

Physical treatment — Mechanical restraint and violence are now foreign to the treatment of insanity the patient may be unrestrained and violent but his treatment may not It is still necessary however to restrain a patient who is bent on harming himself or others and physical force may be the only way of doing so or of giving a patient by tube enough food to keep him alive when he abjures the natural way of eating But force must always be a last resort and chemical substitutes for it seem only a little less of an evil Drugs have their place in the treatment of all kinds of mental disorder but their use easily turns to abuse Whether one is giving morphine and hyoscine in an emergency to an acutely excited catatonic or prescribing aspirin for a mild hysteric the chief danger which must be borne in mind is not over

dosage habituation or suicidal misuse but the habit of stupefying or satisfying a patient with drugs when other means might be taken better suited to his condition Sedative drugs should not be a short cut neither should they be eschewed They should be given when other measures will not serve as for some obstinate form of insomnia anxiety agitation and restlessness or when their use obviates greater troubles *e g* the pulling of bandages from an operation wound The symptoms of intoxication must be watched for with more than usual vigilance when bromide is being given because if unrecognised as such they may lead to certification—for an avoidable drug made psychosis Continuous narcosis for several days with the patient sleeping through 18 or more of the 24 hours is sometimes efficacious in abbreviating an acute attack of mental illness or giving complete rest to an exhausted very anxious person it is not without risk except in skilled hands

There are other drugs to which the above cautions scarcely apply *e g* endocrine preparations remedies specific and otherwise for the physical basis of organic psychoses (*e g* arsenical treatment for syphilis of the central nervous system) and aperients Insulin for promoting hunger calcium for those with hysterical hyper ventilation fits amphetamine (Benzedrine) and acetylcholine for anxiety and a number of substances—from nitrous oxide to amylobarbitone (Amytal)—that relieve catatonic stupor or facilitate psychological enquiry and treatment have all been found useful on occasion Recently hypothermia induced by chlorpromazine (Largactil) has been employed but its value is highly doubtful The same may be said of malononitrile

Three methods of physical treatment have been introduced and widely employed since 1935 namely (1) insulin in large doses to produce hypoglycæmic coma re peatedly (2) convulsant drugs and latterly, electrical stimulation of the brain to bring about fits and (3) surgical incision of both frontal lobes—leucotomy—to sever the connection of the anterior portions with the thalamus Although the former procedures and their many modifications are often referred to by the single ill chosen term shock therapy they have little more in common than that they are crude empirical methods of altering mental disorder for the better their *modus operandi* being still a matter of conjecture Since the insulin method demands skill and experi ence if considerable risk to life is to be avoided it has not been so much used as convulsant treatment Its field of application is schizophrenia especially the early acute forms with good prognosis Convulsant treatment is now given almost always by the electrical method Though first devised for schizophrenia it has limited success there except in the acute stuporose forms and those associated with an affective syndrome Its efficacy in involutional and some other affective disorders is however striking It terminates obstinate melancholias and abbreviates attacks of depression which would otherwise take many months to clear up

Frontal leucotomy has a more insecure place as yet than the other two methods It has been or should be restricted to patients who seem proof against other forms of treatment *e g* those with chronic agitated depression long standing schizophrenia accompanied by violent outbursts or intractable obsessional disorder The pro portion of deaths in a fairly large collection of cases has been between 3 and 4 per cent of recoveries (obviously dependent on the patients selected for operation) about 25 per cent another 40 per cent are said to be clinically much improved about 65 per cent of those operated on do not improve sufficiently to leave a psychiatric hospital The procedure does not reduce formal intelligence but blunts spontaneity and control and may impair judgement and foresight it may lead to epilepsy (in from 4 to 8 per cent of cases) or urinary incontinence Some of the successes attained by the operation in apparently hopeless cases indicate that its uncertainty and crudity do not put it out of court modifications in the site and extent of the cut are still being made with promising results

The three forms of intervention described stand or fall not by appeals to general principles or evidence that they are rational and safe but by proof of their value in

alleviating specific types of mental illness They evoked a somewhat uncritical enthusiasm and hopefulness in some who had previously been given to ill informed nihilism about the prospects of any treatment consequently the mistaken notion has gained ground that before the advent of these methods patients who got well must have done so " spontaneously , and that unless a mentally ill person has had ' shock therapy ' or ' psychotherapy he cannot be said to have had any treatment at all

Exercise or massage and hydrotherapy are beneficial as much for their psychological as for their physiological results the latter, however are not negligible as may be seen in the effect on an excited or an anxious patient of a continuous bath at body temperature The chief importance of diet lies in the frequent refusal of food by patients depressive hysterical, stuporose paranoid, hypochondriacal or overactive Feeding by the nasal or œsophageal tube is a necessity in many such instances after every other method has failed Rarely a special diet is called for as in the symptomatic psychoses of diabetes pernicious anæmia or pellagra and also for some temporary disabilities of the alimentary tract As a rule however such dietetic regime and indeed all physical treatment of localised psychogenic disturbances of function in a bodily system, is an expedient rather than a settled and adequate mode of treatment Many patients with a visceral neurosis (e g effort syndrome) a hypochondriacal preoccupation a hysterical anomaly or a somatic delusion are greatly harmed by the prolonged physical investigation and treatment they receive it confirms the symptom localises it all the more and brings fresh ones in its train Sometimes one has no choice a progressive hysterical contracture a dermatitis artefacta a sore infected by constant picking a tooth loosened by obsessional knocking at it demand treatment

The caveat against lightly resorting to physical treatment of psychogenic anomalies is especially applicable to operative surgery, e g ' cleaning up the septic foci '

CLASSIFICATION

The ideal classification would be on a uniform basis according to the nature of disordered physical and psychological function, or according to innate and external causes Since we do not know enough to do this a mixed ætiological functional and clinical grouping is used It is obviously provisional The chief division is between those mental changes accompanying distinctive somatic disorder and those for which no such physical relationship has been demonstrated The former are called symptomatic, or organic the latter constitutional or functional It is needless to illustrate the point that everything found in the latter may be seen also in the former The reverse of this is not true because there are some symptoms—due to the loss or damage of essential tissues especially in the central nervous system—which can only occur when the material substrate is grossly damaged

Although the functional group is made up of those conditions for which no distinctive somatic disorder can be found responsible it by no means follows that their causes or basis are therefore purely psychological Theoretically such a belief is untenable, since physiological and psychological are only different facets of the same phenomena, and as a matter of observation certain physical disturbances so regularly accompany these disorders and a physical configuration may be so linked with them that there is small doubt that eventually the somatic disturbance of function in them will be well enough worked out for the terms organic and functional to lapse and only the crudity or transience of the physiological changes remain as a point of difference

The first or toxic organic group is large the chief syndromes in it being neurasthenia confusion and delirium and dementia Such phenomena as apraxia aphasia agnosia amnesia and hallucinosis are fairly frequent in this group

The second group comprising three fourths of the recognisable mental illnesses includes the insanities or psychoses and those anomalies outwardly less alien to the normal mind commonly called neuroses The distinction between neuroses and psychoses is at times convenient but without substance To argue whether a dubious case is neurotic or psychotic is like arguing whether a man of medium size is thin or fat he is both and neither A genuine decision as to ætiology prognosis or treatment turns not on whether a case is regarded as neurotic or psychotic, but on more solid findings Since such words die hard the best use of them is to term a patient with mental disorder neurotic if he has fair insight into his illness is co-operative and unlikely to need care in an institution and to term him ' psychotic if the contrary is the case

The toxic-organic group is divided into diseases located in the nervous system and those affecting it indirectly as uræmia or lead poisoning may Some are toxic *e g* delirium tremens some degenerative (senile psychoses) some inflammatory *e g* encephalitis lethargica some plainly hereditary *e g* Huntington s chorea or primary mental defect and some privative *e g* pellagra or myxœdema

The functional conditions are arranged according to whether emotional disturbance is evident and predominant (affective disorder) or whether there is profound derangement of thought, feeling and contact with the real world (schizophrenia) morbid false beliefs have become fixed without intellectual or emotional deterioration (paranoia) repetitive and seemingly irrelevant phenomena hamper mental activity (obsessional) signs of physical or mental ill health especially dissociation readily appear when an unpleasant situation may thereby be escaped from (hysteria)

As will be seen in the special sections, the personality of the patient may also be a criterion of these groupings with the proviso mentioned earlier that illness does not only occur in those with the appropriate psychopathic anomaly of personality nor does the latter by any means regularly issue in definite symptoms Unless however psychiatry takes account of the psychopathic personality even when not accompanied by symptoms of illness it cannot study delinquency disorders of behaviour in children sexual perversions and other anomalies which touch very closely on psychiatric problems in the stricter sense

The following is the classification used here it is much less detailed than that of the International Statistical Classification to which however, it can readily be assimilated

Organic Disorders

- Degenerative and Hereditary Brain Disease
  - (Senile dementia cerebral arterial disease and hypertension Huntington s chorea)
- Syphilis of Central Nervous System
- Other Cerebral Diseases
  - (Lethargic encephalitis Sydenham s chorea disseminated sclerosis cerebral tumour cerebral trauma epilepsy etc)
- Intoxications
  - (Alcohol morphine cocaine bromide etc)
- Infections and Exhaustive Disorders
  - (Infectious toxæmias hæmorrhage etc)
- Metabolic, Endocrine and Visceral Disorders
  - (Diabetes pernicious anæmia pellagra exophthalmic goitre myxœdema tetany pituitary diseases sexual epochs cardiac disease uræmia etc)

Affective Disorder

Excitement
Depression
Anxiety

Schizophrenia
Paranoia
Hysteria
Obsessional Disorder
Psychopathic Personality
Mental Deficiency

Mental deficiency instead of being treated as quite separate from the other classes might logically be distributed among them Most of the feebleminded are probably ' sub cultural that is they represent the lower end of a curve of normal distribution of intelligence throughout the whole population intelligence being here comparable with height But just as there are dwarfs whose brevity is not a physiological attribute but the consequence of disease so there are many defectives (almost all idiots fall into this class) whose low intelligence is the result of demonstrable interference with *cerebral development sometimes from hereditary* and sometimes from environmental causes Members of the sub cultural group which is by far the more numerous have it in common with people of psychopathic personality that they are not con spicuously different from the average population they are not ill and their troubles are partly due to and manifest in their social relationships not least during childhood The pathological groups could be systematically classified according to the disease responsible for their maldevelopment they differ from the other organic forms of mental disorder only in the age at which the damage has been done Congenital syphilis cretinism cerebral trauma encephalitis epiloia cerebro macular degenera tion microcephaly gargoylism *hydrocephalus*, epilepsy Huntington s chorea con genital diplegia a long list can be made of the diseases which will interfere with normal cerebral and intellectual growth, if they can begin to act early enough Custom and convenience however are arguments in favour of keeping all mental deficiency in a class by itself

The above are great clinical groupings types of morbid reaction which are as near to a valid and useful classification as we can get at present There are subordinate symptom complexes or syndromes which are likewise innate and preformed and likewise evoked by circumstances but which are not limited to any one of the major groupings—they are the weft that runs across the psychiatric pattern The most important of these are depersonalisation hypochondria twilight states stupor and other disorders of motility and spasmodic attacks and seizures of different kinds Between symptoms (classified on a psychopathological basis) and the main groupings which best serve clinical purposes these symptom complexes have an intermediate place comparable say to that of mononuclear leucocytosis or coma in general medicine

ORGANIC DISORDERS

GENERAL DESCRIPTION OF TYPES

The varieties of form and course in organic psychosis are essentially few and simple in contrast to the causes which are numerous In other words there is no support for the expectation that to each physical disease there corresponds a characteristic mental disorder It is not possible in an organic psychosis by study of the

mental picture alone to infer its physical cause for that the methods of somatic medicine are needed Many different poisons and lesions may produce the same effect on the mental state Differences depend on the degree and duration of the physical damage and its site which may determine neurological and other symptoms of a typical kind *e g* in G P I or encephalitis lethargica

They are the least constitutional of all mental affections yet even in them con stitutional factors are far from negligible It is due to such factors that one man will show a psychosis with physical illness that in another would lead to no such mental upset and that one patient responds with a manic extravagance to the cerebral disease that makes another patient depressed Moreover hereditary factors can be of great importance in these organic affections as may be seen in amaurotic idiocy or Huntington s chorea

The few syndromes commonly met with here though they are not restricted to organic disease must be described before seeing how particular diseases colour them and determine their course and treatment In organic syndromes a diminution in mental capacity is the central finding To some extent these syndromes may occur also in patients in whom no structural damage can be found as might be expected seeing that the available patterns of structure and function are in all cases much the same

(1) NEURASTHENIA —This term has been over used and ill used like most of the more palatable diagnoses (cf anxiety neurosis) but it need not therefore be discarded now It denotes a form of irritable hypersensitive weakness and depression that is not uncommon after infections exhausting experiences (*e g* hunger lactation in somnia worry hæmorrhage) cranial injuries and chronic poisoning (*e g* with alcohol or coffee) It is true that a clinical picture indistinguishable from it frequently arises where physical causes are unlikely and emotional causes are obvious this clinical finding has the same significance as the fact that the anxiety of exophthalmic goitre is like psychogenic anxiety Just as the anxiety of exophthalmic goitre or constant fear can pass into delirium so can physiogenic neurasthenia be aggravated until it becomes plain *dementia*

The symptoms are partly somatic—active deep reflexes increased sensory irrita bility feelings of pressure on the head and pains in the muscles and elsewhere giddi ness vasomotor lability delayed peristalsis and feelings of fullness in the abdomen diminished libido slight clumsiness and tremor of the muscles of the face tongue and hands On the more psychological side there are feelings of languor and in capacity to concentrate on any mental work doubts as to the accuracy of memory loss of interest slight depersonalisation irritability and tenseness lessened control of emotion and perhaps slight paranoid obsessional or hypochondriac trends This general condition is when physiogenic less influenced by a change in mood than would be the case with psychogenic neurasthenia and the patient is better able to control his motor unrest than his features which are expressive of his agitation The chief reliance however must be put on the history and physical findings for telling whether the neurasthenia is physiogenic or not psychological causes which seem adequate to explain the illness may be deceptive

The course of neurasthenia is towards recovery unless the noxa continues to act where the noxa persists extreme chronicity can result Sometimes an original physical noxa ceases to act but meanwhile other emotional ones have entered the field *e g* unemployment domestic fears and frustrations and so the illness drags on Treat- ment depends on assessment of the causes and the possibility of removing them

(2) DELIRIUM —Delirium most familiar in fevers can also be produced by drugs and other causes of acute cerebral disturbance severe affective disturbance also may be accompanied by delirium Its characteristics are general malaise restlessness irritability and sensitiveness to external stimuli headache anxiety and troubled sleep or insomnia Mild forms of this are met with in so transient an affection as cold in the head Severe forms are marked by illusions and hallucinations of all the special

senses, especially vision Anxiety often becomes extreme and the patient is terrified of his fantastic visions Thought becomes as chaotic and fleeting as in dreams activity is incessant and past *experiences of daily life are revived* as *in the* occupational delirium of alcoholics Attention is weakened and orientation in time and space much impaired There are striking variations in the severity *of the condition in the same patient* it becomes worse in the evening or when the patient has hardly any external stimuli to keep him in touch (cf delirium at night and after a cataract operation) The extent to which consciousness is clouded usually corresponds to the amount of perceptual and affective disturbance Auditory hallucinations occur with clearer consciousness visual ones very profusely with a clouded mind The auditory hallucinations are commonly of an elementary, undifferentiated kind—not *voices* Vestibular hallucinations may occur *e g* of floating in the air Distressing and incoherent ideas pursue each other—ideas of being torn to pieces burnt poisoned buried alive and so *on also ideas of grandeur*

Closely akin to delirium and indeed shading into it is the state of clouded consciousness (or confusion) in which thought is *very incoherent* but the patient is *more* eager to get in touch with his environment than in typical delirium If consciousness is not too grossly clouded the patient is perplexed and troubled by the disordered perceptions through which alone he can learn what is going on about him The picture may be indistinguishable from that seen in some forms of manic excitement and in some catatonic states Differentiation rests not on the immediate psychiatric symptoms but on the history and discoverable causes of the illness The same is true of *acute hallucinosis* in which orientation and grasp are very little impaired but auditory hallucinations—especially threatening sounds and voices—abound and there is a tendency to the *formation of delusions on the basis of these and other perceptual* disturbances The name *twilight state* is applied to another syndrome in which consciousness is changed chiefly because of some powerful affective influence anger or fear may so overwhelm psychic life that the patient cannot grasp his surroundings his thinking is interrupted and slow (except where it falls in tune with the affective disturbance) and his motor behaviour is in keeping with his mood It is as often of psychogenic as of organic origin—one can hardly, for example by direct observation tell an epileptic twilight state from an hysterical one Like delirium and the other conditions just mentioned it is prone to subside and to be followed by amnesia for what happened during *it where there is some recollection* it may be *associated with* a conviction that the hallucinations and other morbid phenomena were real external *happenings*

(3) DEMENTIA —Of all gross encephalopathic syndromes this is the gravest and most typical It corresponds to a diffuse cerebral disease and is made up of intellectual impairment and lessened control of emotion Its form depends so much on the stage of the patient s development at which it occurs that it is customary to consider as dementia only those *cases in which the cerebral damage* has occurred in later childhood adolescence or adult life and to regard earlier cases *e g* cretins as showing mental deficiency or arrest of development *The distinction is rather artificial* at whatever age it be made For convenience only the adult form will be described here *The order in which functions are impaired* corresponds to Hughlings Jackson s principle of dissolution thus recently acquired memories are soonest lost. There is intellectual weakness—the patient cannot reason grasp and remember as he could his attention is less concentrated and sharp his ideas are fewer he cannot take in anything complicated or be sure about time and place he loses himself His emotions are likewise affected—he weeps over trifles in spite of efforts *to control himself* his feelings are shallow and transient, he may be foolishly euphoric, or may burst into anger whenever he *cannot get his own* way There are wide variations in the severity of the condition and its symptoms may be much influenced by the local incidence of the pathological changes in the brain The extent to which various cerebral func-

tions are impaired may differ widely in the same patient a man who seems hopelessly demented may be able to play a good game of chess, while another in whom it is hard to demonstrate any intellectual impairment may micturate into his shoes or do something equally stupid and inappropriate, unexpected sexual misdemenaours are not uncommon in demented persons who do not as yet show gross intellectual damage

Psychological tests have been increasingly used in dementia Although they are untrustworthy for diagnostic purposes they can be of value in measuring the degree and progress of the impairment The most convenient method is that devised by Babcock in which the discrepancy between vocabulary score which is often well preserved in dementia and performance on non verbal tasks is assessed More elaborate differentiation by means of a wide variety of tests is still in the experimental stage

Closely connected with dementia are the *amnesic* syndromes known by the name of Korsakoff Here the memory disturbance is in the forefront The incapacity to receive store and reproduce experience is remedied as it were by lying *i e* the patient confabulates to fill up the gaps in his memory These patients are often ready to adopt suggestions so that one can lead them to tell absurd tales about their recent movements *e g* that they were yesterday in Greenland to see some polar bears They do not show an intellectual damage or incapacity to deal with ideas that is at all comparable in degree to their memory disorder but they are always out in their appreciation of time relationships especially where the present is concerned At first blush they often seem to be behaving like mentally healthy people but one presently discovers that their memory is much impaired their orientation as to space time and personal identity correspondingly poor and their interest and general mood duller than is normal The disorder of memory is never, as in dementia a general weakness reaching back even to childhood

The Korsakoff syndrome is most often seen in alcoholics in whom it was first described associated with polyneuritis but it also occurs in a great variety of organic disorders *e g* intoxication with lead carbon monoxide and other poisons uræmia vitamin B_1 deficiency cranial trauma cerebral syphilis and arteriosclerosis—apoplexy may precede it and the amnesic syndrome be thus complicated by aphasia That it should sometimes follow on delirium is not surprising since in delirium the same memory disturbance is present but covered up by the concomitant excitement disturbance of consciousness and hallucinations Whether a Korsakoff syndrome will clear up depends on the cerebral damage which produces it the alcoholic form occasionally does so eventually in uncomplicated and treated cases

Mental deficiency in some of its forms is a special instance of cerebral impairment as is dementia It is considered for the sake of convenience and tradition in a separate section (see p 1682)

DEGENERATIVE AND HEREDITARY BRAIN DISEASE

There is a group of disorders occurring in late middle life and old age which are clinically and even pathologically near to one another At the one end of the scale is senile dementia at the other climacteric anxiety and depression It includes Pick s presenile dementia Alzheimer s disease cerebral arterial disease and arterial hypertension

The mental disorders of age have displaced schizophrenia and manic depressive psychosis from their position as the mental disorders of highest incidence When first admission rates per 100 000 of the corresponding population have been computed either for senile psychoses or for psychoses with cerebral arteriosclerosis a higher figure has been obtained than for the incidence of all other psychoses

combined, the chances of becoming thus mentally ill therefore are higher in the elderly population than are the chances of developing all other mental illness in any age-group of the population If present trends continue the number of persons over 45 years of age admitted to English mental hospitals in their first attack of insanity will by 1971 approximate to the total number of first admissions of people of all ages in 1937 more than a third of these admissions will be of people over the age of 65 It is not extravagant to say that nowadays insanity is mainly a disease of old age

1 SENILE AND PRESENILE DEMENTIA

Ætiology —Constitutional factors are obviously the most important A tendency to become dotards may be evident in successive generations of a family heredity is held responsible for the wide differences in mental health among elderly people The symptoms of senile psychosis may not be revealed until the patient is exposed to some sudden stress—the death of his wife the need to move house the loss of his occupation, some new set of circumstances Social factors are of great importance Senile psychoses are more common in people with lifelong nervous symptoms or psychopathic personality

Pathology —PHYSICAL —The tissues show the general signs of age, *i e* a diffuse atrophy, which makes the convolutions narrower and the weight of the brain less The nerve cells and fibres are fewer while the mesodermal and neuroglial tissues are increased fatty pigment accumulates There are also, however in senile dementia striking histological features in the grey matter especially of the cortex namely thickening of the neurofibrils which are characteristically twisted and aggregated, and there are remarkable plaques seldom seen except in this condition The main change is probably in the brain colloids so that condensation and coagulation take place the plaques and thickened neurofibrils are secondary to this There is no close correspondence between the kind or extent of the tissue changes and the mental state Plaques and neurofibrils can occur also in the brains of mentally healthy old people

PSYCHOLOGICAL —The previous tendencies of the patients may greatly colour the symptoms Obscure somatic preoccupations and disturbances in time appreciation lead often to fantastic delusions about eternity and what is happening in their body

Symptoms —Memory is poor for recent events the extent of the damage may increase until only the recollections of childhood and early adult life remain People and places are falsely identified with those once familiar and transient pseudo memories are invented Events with a strong affective tone especially if unpleasant, are remembered better The memory of the remote past is not entirely spared even matters of personal identity may at last be forgotten Grasp and judgement the capacity to follow a train of thought and to eliminate the irrelevant are faulty Obstinacy and perseveration go with a rigid adherence to old habits Prolix and garrulous the patient does not recognise how little interest there is for others in his repetitive and ill arranged talk He may partly cover its emptiness with long and sounding sentences on the other hand some patients become monosyllabic because of their failure to find words to express themselves and others again will use a word loosely associated with the one they are vainly seeking or will quite seriously give a punning meaning to a word and even act accordingly (*e g* whistling because You said I could whistle for my money)

There is a narrow range of interests in which food possessions and bodily well being are prominent Grotesque hypochondriacal delusions are common Patients hoard rubbish and are angry if interfered with in this On the whole, however their affective responses are greatly reduced they meet calamities with composure partly due to their failure to grasp what has happened Now and then they show depression and resentment at a slight, and may bear a grudge long after Their activities are

sometimes considerable on the lines of determined rummaging and collecting in others a dull inactivity is all They become dirty and unable to look after themselves This applies as much to those who are excited and active as to the inert The former may fight against being fed and washed, and it is not possible to get them to understand what is being done Delirium and confusional states are prone to occur at night accompanied by fear and bewilderment Sleep is bad and often the patients busy themselves about the place all night long

Legal difficulties arise through the heightened readiness to accept some suggestions (as in the matter of making a will or giving away property) the poorer judgement and the lessened capacity to control sexual desire which is sometimes seen in the early stages Hoarding may lead to petty thieving Occasionally the patient sets fire to the house during his nocturnal prowlings

The symptoms need not be obvious Often the illness has so slowly developed that no one can say when it first passed beyond what is normal in old age An apparent change of character—a kindly man becoming selfish a respectable churchwarden assaulting little girls sexually—may usher it in this is not so much a change in character as a release of primitive trends hitherto controlled The psychosis may take various forms—depressive manic and paranoid In the *depressive* variety there is seldom retardation the affect is rather empty the patient is irritable and hysterical symptoms may be commingled with hypochondriacal ones Ideas of poverty wickedness and disease are often grotesque in their exaggeration—the patient s urine drowns the whole world his body is an undying shell of corruption he is as tiny as a baby—and are monotonously reiterated The *manic* variety is rarer pointless activity and a diarrhœa of words with silly boasting may be accompanied by a disturbance of memory giving a total picture of the Korsakoff type it is sometimes called presbyophrenia Many of these patients have always been of hypomanic temperament their illness may be only slightly progressive and not so severe as to call for hospital care The *paranoid* variety is especially likely to occur in people who have always been of a suspicious turn of mind They hide things because they feel surrounded by thieves and then forget where they have hidden them their failing senses especially of hearing feed their distrust and they project their awareness of sexual impotence or waning intellect Hallucinations and delusions are mingled—gases are pumped into their room their food is poisoned people throw bombs at the house by night greedy heirs are doing them out of their possessions Some of these patients barricade themselves against their enemies or call in the police Whereas the depressive and manic forms are commoner in people with corresponding heredity this paranoid form is genetically often connected with schizophrenia though the distinction between the three varieties is not a sharp or important one The name involutional paranoia has been given to the chronic delusional condition of this type that may develop in single women between the ages of 40 and 52

Bodily symptoms are those of old age especially in the central nervous system where it leads to a slow careful gait with short steps and legs wide apart apraxia and poor co ordination tremulous rather whining utterance small sluggish pupils and occasionally epileptic seizures The disorder of movement is conspicuous in the handwriting—pointed small or erratic in size and sometimes jerky and tremulous

The conditions known by the names of Pick and Alzheimer are to be regarded as atypical senile or presenile psychoses

Pick s dementia consists pathologically of a circumscribed cerebral atrophy mostly in the frontal or the temporal lobe or in both the motor area however is seldom affected nor are Wernicke s zone and the transverse temporal convolutions other areas of the brain especially the parietal may be involved Histologically the ganglion cells are swollen and contain argentophil globules There is a hereditary determinant It is almost twice as frequent in women as in men—the opposite of what has been found to hold for cerebral arteriosclerosis The onset which is

gradual can be at any age from 40 onwards but is usually between 50 and 60 Symptoms depend on the localisation of the atrophy Memory and affect are not impaired till late, they are preserved at a stage in which the patient behaves stupidly—stealing lying or otherwise making a fool of himself Spontaneous attention is poor at first moody the patient becomes dull and unresponsive judgement deteriorates and initiative fails Stereotypies echolalia and repetition of empty phrases monotonous talking and laughing or singing and outbursts of bellowing or whining appear in the later stages There may be aphasia Diagnosis is difficult during life it may be assisted by an encephalogram showing the shrinkage of cerebral tissue from atrophy or by biopsy The condition may last from 2 to 12 years

In *Alzheimer s disease* the senile plaques and neurofibril changes are very numerous The onset may be between 40 and 60 Women predominate Indefinite premonitory symptoms (headache irritability forgetfulness) are quickly followed by progressive dementia aphasia and apraxia are prominent though less coarse and sudden than in cerebral arteriosclerosis In the earlier stages the patients are in fair contact with their environment and look as though they grasp much more than they actually can Their deficiencies are shown up in writing and talking They may be restless and depressed As the disease advances they are less open to affective influences they sink into themselves and say little Stereotyped words or syllables and movements take the place of embarrassed remarks and gestures In the aphasia there is a rather characteristic stringing together of syllables like each other in sound but meaningless Muscular rigidity may lead to contractures The progress of this disease to severe dementia is faster than in typical senile deterioration and the onset is rather earlier

Prognosis —This depends on the previous rate of development of the condition the general physical health of the patient and any special pathological basis *e g* Pick s atrophy that may be recognised Delirious and confusional phases may give a deceptively bad impression for sometimes after they clear up the patient can resume his old routine tolerably well

Treatment —Since the breakdown of old people is often brought about by their inability to cope with the demands and stresses of a society that is organised for younger people social measures can do much to delay the time when senile mental changes will make special care necessary The more satisfying their mode of life the less will maladjustment and gross failure be the effect of their senility Although when senile dementia is clearly evident treatment will partly consist in providing as easy familiar and considerate an environment as possible it would be harmful to leave senile patients idle because they seem listless or to let them be lonely because they are fretful Whether institutional treatment is necessary depends not only on the mental impairment but also on the patient s social level and the willingness of his relatives to look after him well enough Patients often fit surprisingly well into hospital life and routine when this makes due allowance for their infirmities and provision for their social and psychological as well as their physical needs Drugs are best avoided and caution is necessary in letting the patient have the aperients he demands to relieve his—mainly delusional—constipation

2 CEREBRAL ARTERIAL DISEASE AND HYPERTENSION

The characteristic features here are the focal symptoms All else is indistinguishable clinically from senile and other cerebral conditions of course pathologically many senile brains show arterial degeneration too The early or mild symptoms of cerebral arteriosclerosis are the same as those of essential hypertension and very like those of many benign melancholias of late middle age

Pathology —Atheroma of the cerebral arteries is accompanied by nutritional changes—softening—in the brain tissue falling into three stages viz necrosis degeneration (with masses of granular phagocytes containing fats and hæmosiderin)

and sclerosis (in which cavities and scars of glial astrocyte and mesodermal tissue take the place of the necrotic cells) (see also p 1443) The cortex on the convexity of the brain may show microscopic areas of perivascular gliosis but no softening It is not yet possible to correlate the mental and the cerebral changes in these psychoses except for the focal lesions

Symptoms —Since "essential hypertension often precedes definite vascular disease and itself produces mental symptoms a description of these symptoms serves also to describe the earlier stage of cerebral arterial degeneration Along with head ache giddiness tinnitus faintness and insomnia there may be disturbance of speech and writing—the former becoming slow and at times indistinct—and transient pareses and apraxia Certain traits of personality may be intensified the patient becomes irritable egotistic moody and easily tired his conversation lumbers along where once it moved easily he is depressed or paranoid but there may be wide variation in the intensity of these changes which are by no means always found Brief phases of disturbed consciousness lasting up to 3 weeks may suddenly occur either in a form very like the absences of the epileptic or as twilight states with hallucinations ecstasy incoherence disturbed motility and agitation

After this stage of neurasthenia and episodic disturbances the patient with cerebral vascular disease may begin to have trouble in finding words he perseverates a little and is *at a loss when anything unusual is required of him His depression and hypo* chondriacal worries increase he is distressed by his own slowness and failures and may attempt to kill himself Emotional control falls off so that he weeps and storms when he would rather be calm Nihilistic ideas may abound—his bowels have not been opened for 6 months his trunk is a hollow cavity Nocturnal delirium is fre quent Aphasia and apraxia are commonest after a focal complication

The most important feature is the way the patient continues to look normal and sensible when already mildly demented Sometimes transfer to the strange surround ings of hospital is too much for the hitherto well preserved outward normality and the patient goes to pieces as he also may if he has to give up his usual work or move house

Diagnosis —Because a patient has generalised arterial disease it does not follow that any psychiatric symptoms he may show are due to the cerebral vessels being thus affected Unless there are definite focal symptoms or evidence of dementia it is unsafe to hold the cerebral arteries responsible and to give a prognosis based on this There is no known means of distinguishing many benign neurasthenic depressions and involutional hypochondrias from those due to disease of the cerebral vessels If there has not been any history of such tendencies until an attack at the age of 60 odd the probability that it is an organic vascular disease is much higher The dis- tinction is all the more difficult because so many unstable persons develop arterial disease in later life especially those prone to anxiety and other affective disorders Neurological findings (see p 1443) may be decisive in a doubtful case The condition of the retinal arteries is not a reliable guide

Course and Prognosis —In definite cases of cerebral arterial disease with mental disorder the prognosis is necessarily bad though the mental symptoms may only progress slowly and the patient live another 10 or 20 years Much will depend on such sudden accidents as thrombosis or hæmorrhage An episodic confusional state perhaps even one produced by drugs may suggest a needlessly gloomy prognosis In cases of essential hypertension the course of the mental illness is dependent on the general disturbance and is often quite favourable Symptoms that are appar ently hysterical occurring for the first time in middle life are of bad omen

Treatment —Besides the general medical care of such patients not a little can be achieved by psychiatric methods In the early stages where there is much anxiety and depression too energetic physical investigation and treatment may do harm reassurance and sedation can do much good The less said to the patients about

their blood pressure and their arteries the better They should keep at work and in their accustomed surroundings as long as they can, unless an acute phase of the illness or depression intervene Emotional upsets oftener aggravate their condition than physical ones so they should be *cushioned against such jolts* Their depression may necessitate hospital care especially because of the risk of suicide or because they are too irritable and neglectful to be *at home any longer* *If there be dementia* even of mild degree, the patient will probably remain in a mental hospital once he has gone there It is, however, not easy to be sure about *mild dementia being present*, it can be counterfeited by passing disturbances *e g* emotional ones

3 HUNTINGTON S CHOREA (see p 1519)

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

Only the mental symptoms will be described here Hypochondriacal and depressive reactions sometimes *follow* infection or the risk of infection such psychogenic illnesses do not belong under this rubric *occasionally* however a patient s *anxiety lest he be developing neuro syphilis turns out to be justified* A syphilitic neurasthenia can occur in the early stages of the disease due to a mild meningitis The *more severe meningo encephalitis—cerebral lues—may be accompanied by* disturbance of consciousness, even to the point of delirium or mild dementia loss of initiative euphoria or *moroseness poor judgement* and impaired memory may persist and the patient be aware of them in greater measure than he is in general paralysis These conditions are often complicated by the signs of premature arterial degeneration in the brain The psychoses that accompany tabes are due to syphilitic changes in the brain often complicated by alcohol trauma heart and kidney disease and other exogenous factors there are also depressive hypochondriacal reactions to the pains and other disabilities which the patient suffers

General Paralysis of the Insane —Dementia is the constant sign of this mental picture, the old descriptions of a 'classical' course with an expansive onset are fallacious but general dementia is almost certain to occur in every case that is not treated All the other symptoms are either neurological and focal, or due to the patient s constitutional predisposition *and previous experiences*

The dementia may at first be quite undetectable as such because it appears under *the deceptive guise of a neurasthenia melancholia or mania* only gradually does the intellectual impairment become manifest In the beginning of general paralysis which is *seldom* abrupt (though it may need a careful enquiry to verify the prodromal symptoms) functional syndromes can be so typical and organic changes so slight that the most expert psychiatrist is misled only by physical and serological examinations can he avoid a blunder A faint degradation of personality a *lapse* in social refinements may be the first indication of *what is wrong* Then *memory for* the events of yesterday and last week becomes less trustworthy what seemed *at first* a trivial absence of mind becomes serious incapacity and yet the patient remains serene and outwardly indifferent to his lapses As *in senile* and *arteriosclerotic* dementia, he may be all right so long as he is in an accustomed rut, but a holiday or a change *reveals his infirmity* His *mood* and interests as the illness goes on become dull or labile, his rages are fleeting his activities fussy if however he is in a manic excitement, with little dementia as yet the affective changes can be violent *and indeed* dangerous just as in a depressive phase the patient may kill himself *Sleepy and slow*, careless about social usages inattentive and ignorant of what he once knew well the more demented patient cannot escape recognition as having an *organic cerebral* affection Elementary problems in arithmetic and questions of general information are more than he can cope with He gives easy *assurances* that he can do them or

puts his questioner off with airy explanations (*e g* that he has not had his spectacles by him lately) when pressed he makes bad mistakes or becomes angry The extent of his failure will of course depend not only on his dementia but on his previous intelligence and habits (*e g* a bank manager retains the capacity to do mental arithmetic when much else has gone) Inability to receive new impressions and to relate them to earlier memories co operates with impaired judgement to give a gross but patchy and fluctuating amnesia Because of these disturbances and especially the bad judgement patients may commit offences ruin themselves by grotesque extravagance and brush aside facts that stare them in the face They will put up with restrictions on their freedom forgetting their protests soon after making them silly reasons are sufficient for their compliance and a tactfully offered cigarette or joke may divert their thought and feeling from some serious matter that angers them Their delusions are due to the same disorders of memory and judgement coloured by their general personality sometimes they are confabulations rationalisations for their having forgotten or spoilt something If the patient had in health tendencies to euphoria and expansive behaviour grandiose delusions and boasting will be to the fore It is however not uncommon to find a fatuous euphoria though there had not previously been affective swings and hypomania in such patients one finds abundant proof of gross impairment of judgement especially shown as defective insight The most advanced dementia appears as a helpless vegetative bedridden state sometimes accompanied by gross focal symptoms such as aphasia and agnosia The physical symptoms (see p 1455) are much intermingled with the mental ones as in the patient s clumsy movements and disturbed speech and handwriting thus in his writing he leaves out letters syllables and words repeats and transposes them messes the paper with blots and sputters writes across the lines puts in meaningless strokes and leaves his mistakes uncorrected the tremulous script shows interruptions in the usual smooth alternation and tempo of movement the letters are of very uneven size and ill spaced Articulatory and aphasic disturbances may affect the sense intonation timbre rhythm and precision of utterance they must not be evaluated in diagnosis any more than the writing disorder may without regard to the patient s previous normal script and speech and the circumstances under which he was writing or talking since people habitually untidy in their enunciation or handwriting can exhibit many of these symptoms when tired or in a hurry

Besides the above atypical mental pictures may be seen either ordinarily or as the outcome of treatment with artificial fever Paranoid states hallucinosi a Korsakoff syndrome epileptiform excitement hysterical disorders and catatonic symptoms of every kind (except flexibilitas cerea) may occur Hallucinations are uncommon except during fever or after malarial treatment in the latter case they are often of paranoid colouring Not the expansive form but a simple progressive dementia is by far the commonest clinical picture depressive confusional and hyperkinetic states are almost as frequent as the expansive

In the Lissauer form the slowness of the dementia is remarkable in comparison with the conspicuous focal symptoms such as the seizures without convulsions or loss of consciousness

The effects of treatment upon the mental state are of great social moment In many patients who do well the personality has the edge taken off it there may be less initiative and force in mental activity and emotion may be less controlled especially in the proneness to anger or to frivolous levity yet the patient is able to return to his former work even though it is responsible and complex he could scarcely however except in the most favourable cases learn a new job or adapt to new and exacting situations

In the *juvenile* form there may be premonitory symptoms of excitability grizzling timidity and backwardness at school Gradually the symptoms of dementia become plain and if the onset be early enough symptoms usually found in severe

mental deficiency naturally appear such as rhythmic or iterative movements grimaces repetitive chewing and sucking of an automatic kind great restlessness and screaming attacks Simple dementia is the usual form, grandiose ideas are exceptional If the illness begins before the age of 10 or 11 years, speech and writing may be completely lost or reduced to a senseless smattering

For *prognosis* and *treatment* see pp 221 and 1458

OTHER CEREBRAL DISEASES

LETHARGIC ENCEPHALITIS —The mental disturbance of the acute attack may merge into a hyperkinetic excitement, with choreiform and athetoid movements insomnia generalised pains mild delirium and occasionally, catatonic symptoms this seldom lasts more than a few weeks There may be subsequently a neurasthenic fatigue and irritability with headaches and poor sleep The distinction between what is neurological and what is psychiatric in the symptoms could scarcely ever be more difficult than in this disease The motor disturbances such as oculogyric crises are not merely responsive to emotional and other psychogenic influences they are inseparable from concomitant mental happenings (*e g* the surging up of anxiety or obsessions) and whole patterns of complicated behaviour *e g* breathing may be involved The motor rigidity of the patient s Parkinsonian state may be paralleled by a lack of the normal drive and fluidity of thought or behaviour Memory however and grasp are unaffected The obsessional symptoms sometimes occur quite apart from oculogyric crises and may greatly distress the patient Depressive phases may result in suicide which is fostered as it were by the keen appreciation which many patients have of their ruined careers and their almost imbecile appearance, so different from what they were and indeed from what they still know themselves to be Paranoid and especially schizophrenic symptoms may develop in the later stages

The younger the patient the more likely is it that he will develop disagreeable anomalies of personality and have attacks of restlessness or even be permanently restless Many children and adolescents after their acute attack become social problems they play stupid or cruel tricks they set every one they can by the ears they may steal behave sexually in an outrageous way or accuse others of sexual offences against them Their activity is not always purposive nor always antisocial they make the same impression as a monkey might who is sometimes mischievous but always on the move There may be no Parkinsonism in these cases The prognosis is not good and they almost always do better when subjected to the *régime* of an appropriate institution they do badly at home or in places where what may be termed normal delinquents and social problems are cared for

SYDENHAM S CHOREA —The usual mental changes here are lability of affect and irritability These are seen as naughtiness outbursts of anger or crying resentment at sudden noise or light in others there is lessened spontaneity often masked by the choreic movements In more severe cases especially in older children these changes are accentuated in the fleeting phases of anger or terror there may be slight delusional trends Still more severe forms with delirium hallucinations delusions of persecution and much excitement are seen in adults *e g* in chorea gravidarum

The tics and compulsive utterances (Gilles de la Tourette s syndrome) which may follow chorea are evidence of the interplay between hereditary psychic and structural factors Chorea is more prone to occur in those whose families show nervous disorders especially schizophrenia The motor after effects especially tics appear and disappear under emotional influences they are also conditioned by the original choreic disturbance of neuromuscular function The obscene ejaculations of la Tourette s syndrome are dependent on much the same articulatory and respiratory hyperkinesias as are the breathing spasms of encephalitis *lethargica* though

they are also dependent on psychological tendencies and experiences They illustrate how psychological influences work through available bodily structures and functions, whether morbid or healthy The obsessional element in this affection is comparable to that in encephalitis lethargica

DISSEMINATED SCLEROSIS —Slight deviations from mental health are frequent but obvious ones rare in this disease Affective lability may be conjoined with a slight disorder of judgement so that a baseless euphoria develops but this is not universal and many of the patients are depressed Acute outbursts of excitement, hallucinosis or delirium occur in a few cases and dementia in the advanced stages The most important mental disorder in them is that which appears as hysteria A hysterical personality has not been present in these patients before the disease began and the symptoms are in that respect only dubiously hysterical they do however in other respects conform in that they can be evoked psychologically and removed psychologically they may centre on and elaborate actual anomalies *e g* of movement or sensation and may still yield to hypnosis or other psychological measures They can greatly confuse the diagnosis

SCHILDER S DISEASE —In this disease profound dementia gradually develops along with the blindness deafness aphasia and agnosia and other focal symptoms In the juvenile cases there may be at first disturbances of behaviour like those of juvenile encephalitis lethargica

PARALYSIS AGITANS —This may be accompanied by hypochondriacal depression Sometimes this is an expression of the cerebral disease which also causes the Parkinsonism, and in that case the prognosis is bad sometimes it is a recurrence of depressive attacks which have occurred at times of stress earlier in the patient s life and then the outlook is fairly favourable Senile dementia is of course not infrequent in these elderly patients

CEREBRAL TUMOUR —Apart from any aphasia and apraxia the mental state here is more closely related to general intracranial tension than to any local disturbance The size and rate of growth of the tumour are therefore important in this regard If rapidly growing there is more disturbance of consciousness with impaired memory disorientation incoherence and sometimes hallucinations and confabulation this clouding of the mind fluctuates a good deal In more slowly growing tumours lucidity is preserved and change of disposition is the prominent feature The patient s earlier tendencies get freer play unsuspected ones appear and a series of foolish investments for example or homosexual escapades may for years divert attention from the organic disease The moria or fatuous wit and cheerfulness often attributed to frontal tumours but also found in other cerebral diseases may give the impression of being a hysterical pseudo dementia other apparently psychogenic symptoms may prove misleading A straightforward depressive attack can occur or indeed any functional syndrome

Hallucinations may depend on a focal lesion as in the cases in which they are limited to the hemianopic field or are solely of taste and smell

CEREBRAL ABSCESS —*The mental symptoms are those of tumour with or without* others due to meningitis

ACUTE MENINGITIS —There may be delirium preceded during the prodromal stage by irritable apathy and followed by months of moody neurasthenia

CEREBRAL TRAUMA —After concussion there is commonly retrograde amnesia and there may be later also amnesia for events following the injury the extent of this depends on the severity of the damage Delirium may ensue it has little that is characteristic and is more frequent in alcoholic and elderly people A Korsakoff syndrome may develop Twilight states are rather more common during them acts of violence may be committed as in epilepsy and afterwards quite forgotten Traumatic epilepsy may follow The later changes in personality are commonly those that may be found lingering after any toxic or other structural impairment of

the brain But sometimes the disturbance of consciousness is more persistent the intellectual damage greater, the deterioration progressive, in such cases there is usually cerebral arterial disease an unrecognised alcoholism cerebral tumour general paralysis of the insane or some other complicating factor In predisposed persons the cranial injury may be responsible for a melancholic attack, schizophrenia or other functional ' syndrome the prognosis is usually good even if the illness lasts many months

Minor symptoms which may be hysterical occur frequently after cerebral trauma This is partly because of the site of the injury which favours vague physiogenic symptoms that respond readily to emotional and other psychological influences Many of these symptoms are, however, produced by psychical rather than physical mechanisms Not injured cells, but mental attitudes are at the bottom of the tremblings faintings, weakness, paræsthesiæ and other troubles so often the sequel of a trauma in itself little likely to have such effects They are not responses to the actual injury, but to the situation created by the injury It is as unwise to dub all such vague post traumatic phenomena hysterical as to attribute them entirely to the direct injury If there is slight amnesia of the typical kind with difficulty in concentration and head ache it is fairly probable that these are physiogenic residues if there has been an interval between the actual concussion and the appearance of the indeterminate symptoms a history of psychopathic predisposition and an adequate psychogenesis (*e g* economic fears and insecurity or claims for compensation with repeated medical examinations and patent uncertainty among the experts) the condition is likely to be neurotic Much will of course, depend on the neurological and other findings including the demonstration of localised lesions, thus damage to the frontal lobes may much change the personality and in other sites be responsible for an apraxia say or a visual defect Too rigid and doctrinaire an insistence on discriminating neurogenic from psychogenic residues of the injury can be harmful the main matter is to prevent neurotic attitudes and symptoms from developing or if already there from continuing

The degree of intellectual impairment can sometimes be measured and the de parture from normality demonstrated by psychometric methods (see p 1694) Among the tests employed those which require a capacity to deal with abstract con cepts (*e g* sorting objects according to qualities they have in common) are particularly informative

EPILEPSY —Although the motor seizure is the chief symptom of epilepsy and the decisive one in diagnosis there are minor or equivalent symptoms as well as delirium twilight states and dementia to be included among the mental disorders of this illness

Instead of a major fit the patient may become unconscious or he may pass into a twilight state in which for a few minutes or longer he wanders about in a dazed way and does inappropriate things having afterwards complete amnesia for all this, or there may be a sudden interruption of action and speech during which the patient remains immobile or makes some automatic or aimless movements Epileptic furor is a delirious state in which acts of violence may be committed it lasts often for several days is accompanied by disorientation and hallucinosis and is much rarer than is popularly or forensically suppo ed All the states of disturbed consciousness mentioned above are most often seen as equivalents for a seizure the twilight states, however, may precede the motor attack follow it, or be accompanied by a few violent clonic movements

Apart from their seizures epileptics are prone to swings of mood—towards anger shallow sentimentalism or depression—which may pass over into a fugue during which the patient wanders a long way from home

The likelihood of dementia later cannot be inferred from the symptoms of the epilepsy except that it is greater if attacks occur very often *Apparent* dementia may be the result of intoxication with anticonvulsant drugs or of the idleness and sterile

life in an institution When there is genuine dementia it begins as a faint loss of interest and concentration with increased sensitiveness to supposed slights then memory falls off somewhat the trivial and the important are muddled together and the patient talks with much circumlocution he is fond of needless system assumes and parades virtues he has not *e g* an intellectual bias or a devout spirit and is child ishly pleased when anyone praises him Later a profound dementia may supervene but this is not common it is unlikely that the changes of character just described are part of a dementing process many epileptics who exhibit some of the most disagreeable features of this sort never become plainly demented and many severe epileptics are free not only from dementia but also from these traits There is ground for regarding this impulsive pretentious fawning and snarling way of some epileptics as partly a variable expression of their constitutional predisposition (to which the motor seizures are likewise due) and partly as a reaction to their situation Consequently it is much less evident or not evident at all in those who in spite of their fits live comparatively normal lives

MIGRAINE —Occasionally sharp changes of mood behaviour and personality may take the place of the ordinary attack with headache It has often been observed that emotional stress may precipitate an attack and psychological guidance which im proves emotional stability has been found to lessen the frequency and severity of attacks in many patients

INTOXICATIONS

1 ALCOHOLIC DISORDERS

Alcohol is so permissible and trusted a poison so easy of access for those who wish *to escape from their troubles that it is resorted to in excess by maladjusted* persons consequently its effects may complicate or be complicated by the psycho pathic anomaly which favoured the taking of the drug *e g* episodic excitement or depression anxiety cerebral arterial disease paranoid states hysteria The acute effects of a single dose of alcohol are either the well known phenomena of intoxication or an excitement (*mania a potu*) sometimes with clouding of consciousness The excitement is commoner in people with cerebral trauma arterio sclerosis epilepsy or unstable hysterical personality and in them may lead to acts of violence rarely it may occur in normal persons who have taken alcohol when they were exhausted or upset

In chronic drunkards a dementing *demoralisation* can occur Their narrowing of interest superficiality of thought weakness of memory and moral decrepitude are reminiscent of what happens in many epileptics and some early general paralytics The crudeness and even brutality of their conduct is in ill accord with their maudlin prating about virtues and their pot house jollity The mood of these men can be as labile as their abandonment to it is constant they pass from rage to weeping and laugh soon after with no shame for themselves and no thought for the miseries they put on their families Such degradation is of course far from being the rule some chronic alcoholics become only cheap editions of themselves with their former qualities underlined or smudged rather than defaced they are perhaps weak and irritable untrustworthy or lying but not given to savage fury, nor grossly damaged in judgement and social feeling Some of them develop delusions especially of jealousy They collect as paranoid people of other kinds do scraps of alleged evidence which they piece together to prove their suspicions right complicated delusions of persecution however they rarely develop Sometimes the delusions of jealousy fade as the patient gets more and more facile but more often they persist as a chronic insanity and are of the greatest danger to the suspected wife murder is not unknown in such cases

The nature of the delusions is to be attributed in part to the lessened sexual potency of chronic drunkards and to the domestic wretchedness and aversion they often create as well as to the same causes as in "functional paranoid states where such delusions are also common, especially in middle life

The symptoms of *delirium tremens* would appear to differ in nothing but severity from the essential symptoms of any delirium (see pp 1625 1639) Some observers however, deny this The anxiety amounts to terror, mixed oddly enough with euphoria, optic and cutaneous hallucinations are vivid and restlessness can be extreme There is almost complete sleeplessness and much disorientation as to time and place, but not as to personal identity The patient s attention wavers between *his hallucinated and his actual surroundings* but can usually be caught and held for a few moments He is very suggestible, as most chronic drunkards are pressing on *his eyeballs for example will very likely make him see whatever one tells him he* sees and he will read aloud from a blank sheet if one wants him to Among the visual hallucinations *may be miniature ones (micropsia) and many illusional percep*tions The content of the hallucinations changes rapidly and a false perception in one field *(e g a vestibular one) tends to evoke others (e g of sight, touch or hearing)* Insight is commonly lacking, afterwards there is patchy amnesia for what has happened in the delirium The death rate, with adequate treatment has been about 1 in 7 and of those who die most of the men are under 40 and most of the women under 45

In *acute alcoholic hallucinosis* auditory hallucinations of a persecutory kind are prominent and consciousness is not notably clouded It is rarer than delirium tremens and is more prone to follow a bout or orgy of drunkenness The patient is frightened, but not obviously out of his mind, he is correctly orientated and may be able to go about his business for days Auditory hallucinations are vivid and insistent after a premonitory phase in which there are sensitiveness to sounds and roaring singing hissing etc in the ears Tormenting voices sharply localised but seldom fastened upon bystanders abuse threaten or discuss the patient they may say his wife plays him false order him to kill himself describe his every movement especially at private moments in the bath or lavatory cast up his more shameful secrets at him shout his thoughts aloud There may be many voices of men *women and children* all talking together and perhaps rising and falling in the same rhythm as his pulse *They are so real that the patient answers them he may be in doubt* about the presence of his tormentors and may shout back insults to see if a blow will follow from the *owners of these evasive pursuing voices Hallucinations of sight* and other senses are far less prominent than those of hearing cutaneous ones *e g* of being sprayed with a cold liquid are not uncommon Delusions are usually inconspicuous they are, as a rule attempts to account for the hallucinations and they commonly fade out of the picture or pass into a chronic persecutory disorder Flight or acts of violence may result from the patient s fear or anger Usually it is a matter of only 2 or 3 weeks before the hallucinosis clears up if no further alcohol be drunk sometimes however a delusional state more rarely a Korsakoff picture supervenes in predisposed persons After recovery there is little or no amnesia for the events of the hallucinosis Relapse is to be feared if the drinking goes on

The *Korsakoff* syndrome is not invariably associated with polyneuritis Nor as stated on p 1627 is it limited to alcoholism *it can follow other* severe chemical and mechanical injuries to the brain In alcoholics it is commoner in middle life developing either *insidiously in the course of chronic* alcoholic demoralisation, or after delirium tremens women are especially prone to develop this syndrome after *the delirium* The symptoms have already been described The disorientation superficial appearance of clarity incapacity for initial perception and subsequent recall (extending often to most of the material of memory) yet with retention of some capacity for learning by repetition along with confabulation *dullness of emotion*

and initiative and grossly impaired judgement making a striking picture Complete recovery is on the whole uncommon occurring in less than a quarter of all cases The mortality rate is higher in women and older people in those with acute onset and with a red cell count below 3 000 000 or with a rise in the protein content of the C S F It does not correlate with the severity of the peripheral neuritis

Chronic delusional states have been referred to above they are sometimes called alcoholic paranoia but inappropriately so jealousy is the commonest and most dangerous feature Alcoholic epilepsy has been described It is a symptomatic epilepsy often atypical sometimes in unstable hysterical patients it may be brought about through overbreathing when intoxicated

Diagnosis—The diagnosis of alcoholic psychoses must depend much more on a history of drunkenness in any patient than on his clinical psychiatric features none of which are limited to alcoholic disorder Since however alcohol is far the commonest cause of most of the toxic abnormalities described it can be safely presumed in some cases in which the certain history of addiction is unobtainable

Differential diagnosis so far as ætiology is concerned will turn on somatic findings including the results of chemical tests If the form of the disorder is in question the chief diagnostic difficulty arises with acute hallucinosis and the chronic delusional varieties A hallucinosis of similar type can occur in schizophrenia and in affective disorders but in the latter is recognisable by the ideas of self reproach expressed the differentiation from schizophrenia is difficult since in many of the cases the progress of the disorder is towards a chronic schizophrenic psychosis and one may suppose that in these patients the intoxication had activated as it were the same mechanisms as those involved in schizophrenia or had complicated a schizophrenic illness This applies also to the chronic psychosis with delusions of jealousy There is no value in differentiating carefully the clinical varieties of alcoholic psychoses since they overlap

Treatment—Social prophylaxis is the main thing The incidence of alcoholic psychoses in England is less than a third of what it was 40 years ago and this may be attributed almost entirely to social influences Individual prophylaxis is scarcely to be considered save as a by product of psychiatric treatment since a great proportion of unstable persons are potential drunkards and in any case we cannot yet tell which alcoholics will become mentally ill through their drinking Social prophylaxis is so immeasurably better in forestalling alcoholism and the psychoses and degradation that sometimes spring from alcoholism that deliberate individual prevention is here negligible

When alcoholism is itself to be treated independently of its ill effects upon mental health the problem is that of any drug addiction Absolute removal of the drug is essential in the first place This may be effected for a time by getting the patient into a hospital or home where he cannot obtain the alcohol he desires but to ensure that the patient who has had years of excess shall henceforward be able to put aside alcohol while it is within his reach a great emotional upheaval *e g* bereavement religiou conversion fear of death and considerable changes in his human environment are required These are provided for instance by a semi religious organisation of former drunkards called Alcoholics Anonymous which had its rise in America and which has had notable success in the last decade For the most part treatment of alcoholism without restrictions upon access to the drug is a failure the restrictions must at first be imposed from without not left to the patient s self control and judgement Psychotherapy is a necessary feature of the treatment in the many cases in which inner struggles and neurotic disabilities have been the basis for the addiction it must however be conjoined with vigorous social measures (see pp 1618 1619)

Methods which aim at conditioning the patient to have a distaste for alcohol are sometimes successful The unconditioned reflex of nausea and vomiting (evoked by emetine) is linked up with the sight smell and taste of alcohol Thoroughly

The nature of the delusions is to be attributed in part to the lessened sexual potency of chronic drunkards and to the domestic wretchedness *and aversion they often create* as well as to the same causes as in functional paranoid states, where such delusions are also common especially in middle life

The symptoms of *delirium tremens* would appear to differ in nothing but severity from the essential symptoms of any delirium (see pp 1625 1639) Some observers however *deny this The anxiety amounts* to terror mixed oddly enough with euphoria, optic and cutaneous hallucinations are vivid and restlessness can be extreme There is almost complete sleeplessness and much disorientation as to time and place, but not as to personal identity The patient s attention wavers between his hallucinated and his actual surroundings, but can usually be caught and held for *a few moments* He is very suggestible, as most chronic drunkards are pressing on his eyeballs for example will very likely make him see whatever one tells him he sees and he will read aloud from a blank sheet if one wants him to Among the visual hallucinations may be miniature ones (micropsia) and many illusional perceptions The content of the hallucinations changes rapidly and a false perception in one field (*e g* a vestibular one) tends to evoke others (*e g* of sight touch or hearing) Insight is commonly lacking, afterwards there is patchy amnesia for what has happened in the delirium The death rate, with adequate treatment has been about 1 in 7 and of those who die most of the men are under 40 and most of the women under 45

In *acute alcoholic hallucinosis* auditory hallucinations of a persecutory kind are prominent and consciousness is not notably clouded It is rarer than delirium *tremens and is more prone to follow a bout or orgy of drunkenness The patient is* frightened but not obviously out of his mind he is correctly orientated and may be able to go about his business for days Auditory hallucinations are vivid and insistent after a premonitory phase in which there are sensitiveness to sounds and roaring singing hissing etc in the ears Tormenting voices sharply localised but seldom fastened upon bystanders abuse threaten or discuss the patient they may say his wife plays him false, order him to kill himself describe his every movement especially at private moments in the bath or lavatory, cast up his more shameful secrets at him shout his thoughts aloud There may be many voices of men women and children all talking together and perhaps rising and falling in the same rhythm as his pulse They are so real that the patient answers them he may be in doubt about the presence of his tormentors and may shout back insults to see if a blow will follow from the owners of these evasive pursuing voices Hallucinations of sight and other senses are far less prominent than those of hearing cutaneous ones *e g* of being sprayed with a cold liquid are not uncommon Delusions are usually inconspicuous they are as a rule attempts to account for the hallucinations and they commonly fade out of the picture or pass into a chronic persecutory disorder Flight or acts of violence may result from the patient s fear or anger Usually it is a matter of only 2 or 3 weeks before the hallucinosis clears up if no further alcohol be drunk sometimes however a delusional state more rarely a Korsakoff picture supervenes in predisposed persons After recovery there is little or no amnesia for the events of the hallucinosis Relapse is to be feared if the drinking goes on

The *Korsakoff* syndrome is not invariably associated with polyneuritis Nor as stated on p 1627, is it limited to alcoholism it can follow other severe chemical and mechanical injuries to the brain In alcoholics it is commoner in middle life developing either insidiously in the course of chronic alcoholic demoralisation or after delirium tremens women are especially prone to develop this syndrome after the delirium The symptoms have already been described The disorientation superficial appearance of clarity incapacity for initial perception and subsequent recall (extending often to most of the material of memory) yet with retention of some capacity for learning by repetition along with confabulation dullness of emotion

Prognosis —This is poor as regards recovery from the addiction especially if *the patient s profession makes access to the drug easy The more normal the patient s* personality the better the outlook After apparent cure however relapse is frequent and the outlook is then correspondingly worse unless the patient can be stopped from getting the drug Many morphine addicts also take alcohol cocaine and such other drugs as they can get Suicide with morphine is not uncommon for obvious reasons Death is sometimes the result of cutaneous infections especially when the patient is grossly undernourished

Treatment —This must be in an appropriate institution, general hospitals seldom have the necessary facilities Treatment at home is bound to be a failure It should be impossible for the patient however skilled in stratagems to get hold of morphine He should if possible contract to stay for at least 2 months The withdrawal of the drug should be abrupt and total except in very debilitated patients, tapering off prolongs the distressing period of withdrawal symptoms and gives *opportunity* for the patient to develop psychopathic reactions and *dodges* If the patient s condition demands a gradual withdrawal this need seldom extend over more than a fortnight When an abrupt end has been put to the taking of morphine the rigours of the first 4 or 5 days (after which the worst is over) can be alleviated by sedatives in fairly large doses copious fluids warm baths massage and fresh air gastric lavage and alkalis help and for circulatory symptoms caffeine may be given with small doses of morphine also in very severe cases Insulin in subcoma doses has been used to ease the period of withdrawal After this phase is past sleeplessness may still be intractable in giving sedatives or hypnotics for this barbiturates and paraldehyde with occasional doses of hyoscine are the safest but should be used sparingly with frequent changes and it need hardly be said complete refusal to let the patient know what he is having Psychological treatment is of great importance but there is no specific technique applicable to this addiction To be successful the *psychological* treatment requires the co operation of the patient s *family* as well as of the patient himself who will be well advised to keep in touch with his physician for years The great difficulty of getting the drug in this country because of the vigilance of the Home Office is an immensely favourable factor after active medical treatment has ceased It is wise for the patients to eschew alcohol and of course all hypnotic drugs

3 OTHER INTOXICATIONS

Cocainism and Cannabis addiction are rare in England The causes and symptoms are similar to those of other addictions *e g* alcohol and morphine Deliria hallucinations Korsakoff syndrome or demoralisation can occur in the former conditions microptic and cutaneous hallucinations *e g* of bugs under the skin are prominent A paranoid schizophrenic state sometimes comes on usually clearing up after the drug has been *stopped In treatment what was said of morphinism mostly applies* here though withdrawal symptoms are less severe

Bromide intoxication often passes unrecognised All the organic syndromes can occur usually as complications of a pre existing disorder for which the bromide has been prescribed A delirium and a paranoid confusional state or lachrymose amnesic syndrome are the usual forms In the more long standing and severe forms cachexia circulatory failure and even death may occur Acne and other physical signs of intoxication or idiosyncrasy may not be evident Diagnosis rests on the history and the amount of bromide found in the blood more than 50 mg per 100 ml being indicative of a considerable intake or retention of bromide Treatment consists in complete withdrawal of the drug promotion of its excretion by giving sodium chloride and fluids in large quantities and general physical and psychiatric measures

Barbituric acid derivatives such as barbitone (Veronal) and phenobarbitone (Luminal) can in rare cases lead to apparent euphoric dementia likely to be mistaken

carried out the method has yielded fairly good results, half of those treated are reported as still abstinent 4 years afterwards It is impossible however, to benefit the addict who does not seriously want to stop drinking In a small proportion of chronic alcoholics amphitamine sulphate is said to diminish the craving

A drug which may help the patient s efforts to remain abstinent is disulfiram (Antabuse) taken daily by the mouth this ensures that a drastic reaction will ensue if the patient drinks any alcohol since acetaldehyde is then liberated within the circulatory system Knowledge of this very disagreeable consequence deters the former addict from drinking but he can evade the risk if he wants to by ceasing to take the drug It is *therefore pointless to administer it unless the patient sincerely wishes to be abstinent* The risks of the method and its dependence upon the patient s co operation make it desirable that it should be initiated in hospital and undertaken only as part of a general plan of treatment and rehabilitation

The grosser mental disorders due to alcohol need hospital treatment Delirium tremens should be treated as far as possible without hypnotics which have little effect upon the excitement and sleeplessness unless employed in dangerous doses if any paraldehyde or hyoscine should be used Circulatory failure and accidental self injury are most to be guarded against The continuous bath at body temperature is sometimes beneficial, otherwise the patient should be in bed with a minimum of necessary restraint under the care of an experienced nurse and ensurance of adequate diet—mainly fluids and glucose and large amounts of thiamin or the whole vitamin B complex No alcohol should be given Occasionally lumbar puncture is helpful Insulin and corticotrophin have been found beneficial but the evidence is not impressive

Especial care must be taken against the early discharge from hospital of alcoholics with delusions of jealousy If they have been certified they may add a deep resentment on this score to their other grounds of morbid hatred, and there is grave danger that they may, if they resume drinking attack their wives murderously

2 MORPHINISM

Only the effects of this belong among the organic disorders its causes and the incapacity of the addict to escape from it are due to social and intrinsic factors not *to any physical damage* Weak *unstable unhappy people e g* many homosexuals are most likely to become addicts it is rare to meet an addict who has not shown pronounced psychopathic traits before his addiction began and few of those who profess to have been seduced into the habit by more or less injudicious administration of morphine for some pain they had are in that telling the whole truth Yet it is a wise caution that withholds morphine from all chronic disease *that is not hopelessly* progressive and hesitates to prescribe it at all for those whose personality or opportunities make the risk of addiction greater

Symptoms —These are not at first noteworthy unless the patient be seen during the next 2 or 3 hours after he has taken his drug The symptoms of withdrawal sometimes severe are more likely to occur in those whose tolerance has been raised by the habit they consist of yawning sneezing overflow of tears and saliva fullness in the head then restless movements malaise twitching in the face tremors palpitation *indigestion vomiting diarrhœa strangury*, sleeplessness and circulatory upset which may go on to collapse

It is difficult to judge how far the drug itself is responsible for the demoralisation that is met with in chronic morphine addicts probably as important in causing it are the psychopathic personality of the addict and the underhand life he must lead Laziness and lying are frequent and the patient may resort to subterfuges or even crimes *to get his drug* Dementia does not occur delirium is rare The physical effects of chronic morphinism are dryness of the skin hair and nails constipation and anorexia partial impotence and poor resistance to infection

METABOLIC, ENDOCRINE AND VISCERAL DISEASE

1 METABOLIC DISORDERS

Various metabolic disorders can similarly i e non specifically affect mental health *Diabetes* for example which is especially frequent in families with a pre disposition to affective psychosis may be accompanied by transient phases of depression, anxiety or excitement which correspond to changes in the blood sugar level or a ketosis may be ushered in by mild delirium A diabetic pseudoparesis with peripheral neuritis may cause slight difficulty in diagnosis In children mild hypo glycæmia may be responsible for anxiety naughtiness and other disturbances of behaviour Anomalous psychic states may be produced in the rare condition of hyperinsulinism and be mistaken for hysteria or an anxiety state of the psychogenic sort *Gout* may occur in people predisposed to affective disorder often a depressive phase precedes an attack Alkalosis and anoxæmia may each be the cause of mental disturbance of the organic type In *pernicious anæmia* there may be symptoms e g an acute confusional state referable to the structural changes in the central nervous system but more often depression occurs without organic features mania can also occur and in some cases a chronic paranoid condition The more organic the picture the poorer the prognosis for a return to mental health Of deficiency diseases *pellagra* is the one most commonly productive of mental disorder It must be remembered that a long standing anorexia of psychogenic origin or occurring in the course of a chronic melancholia may itself lead to a pellagroid condition so that the symptoms of mental disorder will then be those of the original illness plus those due to the deficiency The clinical picture is sometimes very like that of hysteria or the usual organic syndromes may be produced especially florid confusion with perhaps hallucinations of fire The nutritional factor in alcoholic psychoses especially Wernicke s encephalopathy is prominent

In the metabolic di orders just mentioned the physical phenomena are relatively coarse and obvious It is in some cases proven and in others highly probable that less obvious metabolic disturbances are among the primary symptoms of functional mental illness or are its pathological basis The acid base equilibrium and the electro lytes of the blood the metabolism of carbohydrate fat and protein and the chemical regulation of the vegetative activities are all in such forms of mental illness as schizophrenia and mania subject to changes which have not as yet been used in the path ology or treatment of these conditions because the findings are not sufficiently constant or specific

2 ENDOCRINE DISORDERS

These play a more prominent role in the investigations than in the clinical practice of psychiatry Many endocrine preparations have it is true been administered to schizophrenic sexually perverted and melancholic patients either empirically or in accordance with a premature and ill devised theory but the good results of all this are negligible Œstrogen treatment of menopausal neuro vegetative symptoms is a rational procedure but the blind use of endocrine substances in psychiatry has had its day

Exophthalmic goitre is more prone to occur in anxious nervous people especially after some sudden shock The usual concomitants—restlessnes tension irritability difficulty of concentration and liability to sudden changes of mood—may be complicated by a definite mania or depression and if the disease be severe or advanced delirium and confusion may supervene Though such organic syndromes mean as a rule a bad prognosi they sometimes clear up dramatically after operation The interaction of constitutional and psychogenic factors with the actual thyrogenic

for general paralysis because of the ataxia tremor articulatory disorder and other neurological signs Recovery is the rule when the drug is stopped Picrotoxin may be needed for acute poisoning For the addiction itself essentially the same problems and methods of treatment are in question as with other drug addiction This applies also to *ether*, *chloral* and *paraldehyde*

Mercury and *lead* poisoning may lead to mental disorder (see pp 368 and 382), *manganese* to a Parkinsonian syndrome with compulsive symptoms (reminiscent of encephalitis lethargica) and a mild paranoid or euphoric dementia, and *benzene* or *carbon disulphide* may cause delirium

Acute carbon monoxide poisoning in rare instances leaves behind severe mental disorder of the amnesic aphasic kind, which may not become apparent until several weeks after the recovery of consciousness More commonly it results in a clinical picture almost indistinguishable from hysteria this may take months to clear up and is in no wise benefited by psychotherapy Chronic poisoning by small quantities of carbon monoxide causes neurasthenia

INFECTIONS AND EXHAUSTIVE DISORDERS

1 INFECTIOUS TOXÆMIAS

Delirium and a Korsakoff syndrome are the more acute, and neurasthenia the milder signs of mental disorder due to an infectious fever In many of the cases however in which mental disorder is attributed to sepsis or other infection either the mental changes are unconnected with the infectious process or there has not been an infectious process as is often found when one enquires into an alleged attack of influenza' and finds it was nothing of the kind There are three possibilities the mental changes are mainly due to the infection they are independent of the infection they are partly due to the infection and partly to other, usually constitutional causes The depression that occurs in and after many infections is usually of the third category mentioned, delirium instances the first possibility, and the second is often exemplified when some non organic syndrome is put down to sepsis *e g* in the tooth sockets

Wherever a delirium or other mental disturbance of one infection differs from that of another *e g* the delirium of typhoid from that of pneumonia the difference lies only in the severity and duration of the physical effects of the intoxication and in the peculiarities of the affected person no mental symptoms specific to any one infection can be demonstrated Among the individual peculiarities just mentioned must be included a constitutional predisposition or readiness to respond with symptomatic psychoses to mainly physical ills

There are a few infections that hardly ever cause mental disturbance *e g* tetanus and diphtheria others do so by their local cerebral incidence *e g* malaria or encephalitis lethargica *Tuberculosis* from its chronicity and its occasional incidence on the central nervous system has a special position Its treatment moreover especially in the pulmonary form necessitates an abnormal unsatisfying life for a time and this with the toxæmia seems to be responsible for euphoric or anxious restlessness in which erotic tendencies and irritability are often prominent Spes phthisica is partly attributable to toxic euphoria in part it is a form of over compensation for fear

2 EXHAUSTION AND INANITION

These especially if conjoined with some shattering experience—an earthquake incessant bombardment a bereavement—bring about severe mental disturbance *e g* a twilight state or a delirium Hæmorrhage and cachexia may be responsible for light headedness as in advanced carcinoma or after a severe operation

METABOLIC, ENDOCRINE AND VISCERAL DISEASE

1 METABOLIC DISORDERS

Various metabolic disorders can similarly, *i e* non specifically affect mental health *Diabetes* for example which is especially frequent in families with a pre disposition to affective psychosis may be accompanied by transient phases of depres sion anxiety or excitement which correspond to changes in the blood sugar level or a ketosis may be ushered in by mild delirium A diabetic pseudoparesis with peripheral neuritis may cause slight difficulty in diagnosis In children mild hypo-glycæmia may be responsible for anxiety naughtiness and other disturbances of behaviour Anomalous psychic states may be produced in the rare condition of hyperinsulinism and be mistaken for hysteria or an anxiety state of the psychogenic sort *Gout* may occur in people predisposed to affective disorder often a depressive phase precedes an attack Alkalosis and anoxæmia may each be the cause of mental disturbance of the organic type In *pernicious anæmia* there may be symptoms *e g* an acute confusional state referable to the structural changes in the central nervous system but more often depression occurs without organic features mania can also occur and in some cases a chronic paranoid condition The more organic the picture the poorer the prognosis for a return to mental health Of deficiency diseases *pellagra* is the one most commonly productive of mental disorder It must be remembered that a long standing anorexia of psychogenic origin or occurring in the course of a chronic melancholia may itself lead to a pellagroid condition so that the symptoms of mental disorder will then be those of the original illness plus those due to the deficiency The clinical picture is sometimes very like that of hysteria or the usual organic syndromes may be produced especially florid confusion with perhaps hallucinations of fire The nutritional factor in alcoholic psychoses especially Wernicke s encephalopathy is prominent

In the metabolic disorders just mentioned the physical phenomena are relatively coarse and obvious It is in some cases proven and in others highly probable that less obvious metabolic disturbances are among the primary symptoms of functional mental illness or are its pathological basis The acid base equilibrium and the electro lytes of the blood the metabolism of carbohydrate fat and protein and the chemical regulation of the vegetative activities are all in such forms of mental illness as schizo-phrenia and mania subject to changes which have not as yet been used in the path-ology or treatment of these conditions because the findings are not sufficiently constant or specific

2 ENDOCRINE DISORDERS

These play a more prominent role in the investigations than in the clinical practice of psychiatry Many endocrine preparations have it is true been administered to schizophrenic sexually perverted and melancholic patients either empirically or in accordance with a premature and ill devised theory but the good results of all this are negligible Œstrogen treatment of menopausal neuro vegetative symptoms is a rational procedure but the blind use of endocrine sub tances in psychiatry has had its day

Exophthalmic goitre is more prone to occur in anxious nervous people especially after some sudden shock The usual concomitants—restlessness tension irritability difficulty of concentration and liability to sudden changes of mood—may be compli cated by a definite mania or depression and if the disease be severe or advanced delirium and confusion may supervene Though such organic syndromes mean as a rule a bad prognosis they sometimes clear up dramatically after operation The interaction of constitutional and psychogenic factors with the actual thyrogenic

intoxication makes some treatment of the anxiety by psychological as well as other methods desirable in many cases of exophthalmic goitre either as a preliminary or supplement to partial thyroidectomy

In adult *myxœdema* the slowing of mental activity may sometimes be accompanied by a chronic paranoid psychosis or there may be a phase of excitement with hallucinations the variety of syndromes that can occur is referable to pre existing constitutional tendencies and to the varying severity and rapidity of development of the thyroid deficiency An apparently 'functional' syndrome *may precede the* overt *myxœdema*

Juvenile and congenital myxœdema are described elsewhere (see p 496)

Tetany may be signalised by epileptiform seizures or there may be a proneness to psychogenic fits thus the patient may spontaneously overbreathe until a convulsion is induced *Hysterics sometimes* use hyperventilation in this way In severe tetany a resistive lethargy or an excited incoherent confusion may occur

Pituitary diseases are more often accompanied by mental symptoms that are a comprehensible *reaction to the* physical symptoms than by organic syndromes, the latter when they occur may be due to increased intracranial tension In acromegaly depression reserve touchiness and irritability are not surprising though some acromegalics remain cheerful as long as their disabilities are moderate and sometimes there is a blindness to the disease a lack of insight even when it is advanced In dystrophia adiposo *genitalis a rather childish* placidity may be met In adiposis *dolorosa depression may be severe or hysterical symptoms may develop Simmonds s* disease may be accompanied by depression severe anorexia reaction to the psychosexual disturbance and in the later phases by organic syndromes due to the cachexia Similarly, disorders of pituitary function have been found in some cases of anorexia nervosa In Cushing s basophil syndrome depression and other mental disturbances can occur

Addison s disease is accompanied by a neurasthenia of which for a time the physical basis may be quite overlooked (as may also occur in myasthenia gravis), *in the later* stages delirium has been known to occur

Acute anxiety attacks may occur from a phæochromocytoma Some persons during the course of treatment with cortisone or corticotrophin develop an acute psychosis which clears up if the drug is withdrawn

Sexual epochs may in women be associated with mental disorder of the organic type *e g* some psychoses of pregnancy and the puerperium During pregnancy plain psychosis is rare, but hysterical symptoms depression and anxiety *are fairly* common, especially if the mother is reluctant to have another baby a gross psychosis may however, break out during the latter months of pregnancy The organic mental syndromes may develop along with polyneuritis eclampsia or chorea gravidarum Termination of the pregnancy is called for on account of the mental condition when there are symptoms of organic psychosis which are likely to get worse a history of suicidal attempts or infanticide in connection with previous pregnancies and a depression again in this one or if on other grounds there is a *clear risk of suicide or* other untoward result of the mental illness should pregnancy continue The decision is often a very difficult one requiring an expert knowledge of psychiatry for the careful appraisal of ætiology and prognosis essential in every case The question must turn mainly on the therapeutic value of terminating the pregnancy so far as the mother s mental state is concerned as well as upon the stage of pregnancy reached

In the puerperium 'functional' psychoses often develop in predisposed women if there be septicæmia as well a confusional state or a delirium *followed by a period* of neurasthenia may occur In many cases the delirious puerperal psychosis clears up in a week or two the more endogenous varieties have sometimes a less satisfactory outcome than their form and onset suggest Infanticide may occur in a puerperal psychosis especially if the mother has while pregnant felt resentful at

having a baby or been troubled by murderous preoccupations *e g* obsessions Psychoses of lactation are rare and seldom of the organic type Menstruation is apt to be associated with depression irritability and languor in many women especially during the few days before the period begins there are no menstrual psychoses but the liability to suicide and to psychopathic reactions is somewhat higher at this time There is no satisfactory evidence that the affective disorders of later middle life (involutional melancholia ') are caused by the endocrine changes of the menopause they are certainly not benefited by œstrogen therapy Puberty and the climacteric are periods of stress during which schizophrenic and affective disorders may occur The effects of castration are dependent on the age at which the gonads are removed intellectual development is unaffected but the emotional and conative activities of those castrated in adult life may be impaired Neurasthenic symptoms are frequent and in women anxiety symptoms may appear

3 VISCERAL DISEASE

This may be directly responsible for mental disorder of the organic type Thus *cardiac* disorders predispose to an anxiety which at night may take the form of mild delirium with restlessness terror disorientation and auditory and sometimes visual hallucinations With improvement in the circulation the mental symptoms disappear or remain only as a moody unrest Reference has already been made to arterial hypertension (see p 1630) The connection between *alimentary* disorders and neurasthenic states is well attested and is striking in children Jaundice may be accompanied by severe depression but seldom leads to delirium save in the case of acute yellow atrophy *Uræmia* may disturb consciousness greatly in the form of any of the organic syndromes from a twilight state to a euphoric dementia, a Korsakoff condition can occur but is infrequent

The psychological causes or accompaniments of many visceral diseases have been diligently studied and the conditions in which they appear prominent are sometimes called psycho somatic The problems raised are intricate and the interplay between the physiological and the psychological aspects of the disease processes has not as yet been fully disclosed in any of the major conditions studied *e g* ulcerative colitis peptic ulcer bronchial asthma

AFFECTIVE DISORDER

This is of three types

1 Manic excitement and hypomania
2 Melancholia and mild or neurasthenic depression
3 Agitated depression and anxiety state

There is in each case a major and a minor form Each is related to a more or less characteristic personality and for each the cause of occurrence may be chiefly environmental or chiefly hereditary Combinations are frequent (mixed forms) or there may be successive appearance of the different types often with an interval between the attacks A benign outcome or periodic course is the rule for the major forms but not for the minor which often tend to become chronic This is partly because the environment can have more influence whether for good or bad on the course of the minor than of the major more explosive and sweeping forms It would be a very convenient thing if endogenous cases could be sharply differentiated from psychogenic ones as in the Kraepelinian scheme but it cannot be done

Ætiology —INTRINSIC —Heredity is the most constant single cause Research has been mainly into the major manic depressive cases The genetic factor is weakly

dominant It may be that more than one gene is concerned but this is hard to tell, because the predisposition to an affective disorder may be latent in persons who have not been subjected to the stresses that would make it manifest, and consequently the usual Mendelian figures are not to be expected The present state of knowledge is illustrated by studies on manic depressive twins among whom 69 per cent of those monozygotic (*i e* with identical heredity) were alike affected with the disorder while the corresponding figure was only 16 per cent for the dizygotic pairs (*i e* with dis similar heredity) In the 31 per cent of monozygotic twin pairs who were not alike in respect of mental illness, the difference must have lain in the environment thus showing the relative importance of external factors in causing the inherited tendency to become manifest Although not manifest as illness the inherited tendency may express itself in bodily and mental constitution

The bodily habit that is found in a majority (not the overwhelming majority) of those with affective psychoses is called pyknic or eurymorph It is best seen in men after the age of 30 It is characterised by large visceral cavities (head thorax, belly) a tendency to fat on the trunk slender shoulder girdle and extremities stocky build a broad face on a short massive neck thick receding hair and later, baldness venules on the cheeks and a disposition to arthritis gout diabetes and especially arterio sclerosis As this John Bull build is so common in mentally healthy people it cannot be regarded as a precursor of mental illness but only as an indication that some of the constitutional and genetic causes or biological requirements for affective psychoses are present

The same is true of the mental constitution or personality Here there are several groups shading off on the one side by way of cyclothymia and other intermediate forms of mild disorder into definite affective psychosis and on the other into normal and stable personality There are those with a pervading gloominess pessimism and feeling of insufficiency that spoils their lives others who are for ever anxious keyed up wondering whether something has gone wrong or will go wrong and whether it is their fault—careworn worrying creatures while a third group is made up of the lively enterprising confident sociable people whose euphoria is patent Irritability may be found in any of these groups especially the second and the last Contrasted or different features are often found mixed in the same patient The most striking characteristic of the personality of manic depressive patients is their ready responsive ness and lability of mood they fluctuate with their surroundings and in many in stances pass suddenly and with small occasion from one mood into another far removed from it

The signs of affective illness may appear in childhood though major outbreaks of mania depression or agitation are rare before puberty When these occur the phases are usually brief and the environmental influences strong Milder forms are often regarded as normal since night terrors and other fears mischievous gaiety and sulky gloom are all familiar enough in children it is the degree occasion and persistence of the affect which must decide whether it is morbid

The psychological crises of puberty are only occasionally affective—chiefly self reproachful depression or agitation—but during adolescence the illness becomes more frequent it seldom however calls for mental hospital care Each menstrual period may be accompanied by *depression or restlessness usually coming* on about 2 days before the period In the third decade of life the number of cases steadily rises and there is another peak in frequency between the ages of 45 and 55 The latter in volutional cases show the influence of age strikingly so much so that they are often *considered as separate disorders*

There is little to choose between the curves of age incidence for morbid depression and morbid anxiety of whatever degree for mania the frequency is highest before the age of 30 as also for affective illnesses with a strong confusional flavour Preg nancy is frequently accompanied by depression and agitation psychological factors

are mainly responsible After childbirth though there be no septicæmia affective illness can occur running a typical and often lengthy course

The female climacteric is a time when anxiety usually mounts and is accepted as an ineluctable effect of the change It may become definite illness persisting even for 2 or 3 years It is doubtful whether there is a specific connection between the endocrine causes of the menopause and so called climacteric insanity the melancholia then coming on is like the melancholia of 5 or 10 years later or the melancholia of middle aged and elderly men in whom the endocrine changes are not the same The influence of sex as a whole is obscure Women have this illness more than men though the manic form is relatively more frequent in men The reactivity is often greater and the syndrome less clear cut in women

There are geographical differences sometimes thought to be racial in the incidence but the little that is known points to environmental rather than intrinsic causes for this It has been suggested that affective psychoses are commonly linked with high intellectual gifts another says they have affinity with mental defect The former statement has better support than the latter but both probably are fallacies depending on the material selected for study

EXTRINSIC —*Physical* —Chronic toxæmia and acute infections especially influenza and pneumonia can be responsible for the illness Various drugs help to heighten the anxiety to a morbid degree *e g* alcohol in certain circumstances insulin or hyoscine Cerebral trauma may provoke an attack The list of physical factors could be much added to but it must be borne in mind that wherever a distinctive rather than incidental physical cause can be found the condition passes over into the category of organic psychoses The most difficult cases in practice are those in which there is a question of cerebral arterio sclerosis or exophthalmic goitre the affective disorders indisputably due to these two diseases may be quite indistinguishable from others for which there is no such organic basis The problem here is clinical rather than fundamental since vascular cerebral endocrine and autonomic functions are particularly concerned in the mechanism of emotional change certain disturbances of the physical apparatus will necessarily be accompanied by many of the psychological phenomena of these emotional changes The depression of paralysis agitans and the anxiety of coronary disease are of the same order The notion that coitus interruptus and other sexual practices produce anxiety is unfounded but they may contribute to it by psychological means

Psychical —A recent misfortune commonplace or tragic may be the cause Any calamity to which human beings are liable may provoke an affective breakdown Sometimes it is induced by the insanity of a close relative However trivial it seems to outsiders the event that has precipitated an affective attack has been felt as a catastrophe by the patient there are no records of great and sudden happiness causing an affective psychosis The nearest approach to a specific connection between the precipitating happening and the type of affective illness is seen in the anxiety disorders which follow a terrifying experience such as exposure to shell fire and bombardment from the air morbid depression following bereavement financial setbacks or degradation is an understandable response it is true but to ascribe the type of response directly to the nature of the experience is specious since on another occasion it may be with hilarious mania that the calamity is met

Moreover the experiences of a lifetime will have determined what calamities are most felt they need not be calamities in other people s eyes at all Experiences spread over years are the common extrinsic cause of the more chronic neurotic forms of affective illness this applies least to chronic hypomania In these chronic conditions the patient s own behaviour has so much to do with what happens to him as it were from outside that to separate extrinsic from intrinsic is very hard

Pathology —The *physiological* changes are characteristic only of emotional disturbance not of morbid emotional disturbance and therefore they are not of

diagnostic value They consist in lability of blood pressure and pulse rate abnormal motility of plain muscle especially *in the alimentary tract* carbohydrate disturbances variations in either direction of the rates of salivary and other secretions and decreased psychogalvanic activity The changes are variable from patient to patient and are not always discoverable More significant are changes in basal metabolism weight sleep and menstruation loss of weight is the rule during the illness Irregularity of menses and then amenorrhœa often occur Rise in the blood iodine content changes in the K/Ca ratio diminished cellular respiration hypercholesterinæmia and signs of adreno cortical hyperactivity have been alleged but not conclusively

The *psychological* changes, in spite of great external differences have the following in common the morbid phenomena are in accordance with the prevailing mood, though not wholly derivable *from it thought is less purposively directed to im* personal ends than it would normally be, but more purposively to personal ones there is a small number of topics of preoccupation in each patient but his ways of arranging and embellishing them can be many the whole body (or parts of it) often receives much of the patient s attention because of more or it may be less feeling in it (hypochondria depersonalisation) misconstructions abound with consequent ideas of self reference and persecution as well as misidentification and there is a feeling of inner tension unrest and excitement however apathetic or carefree the patient s demeanour

The seemingly greater quickness and capacity of manic patients has not been confirmed by psychomotor, intellectual and association tests *hypomanic patients* sometimes however, do better than in their normal state This can be compared to the effects of increasing doses of alcohol Patients with affective disorder are more irritable and excitable than is normal Time appreciation may be grossly disturbed personal time seems to pass very differently from clock time time may seem to stand still, no future is conceivable Perplexity may be conspicuous and explanations of this in terms of Gestalt psychology conditioned reflexes and toxæmia have been proffered

The effects of experience in bringing about this illness cannot be explained in terms of a logical and coherent system unless one accepts the premises of that system and infers what cannot be observed Consequently as there are several such psychological systems there are several explanations They state the conjectured ways in which instinctual energy or libido may become misdirected because of environmental conditioning frustration and loss

Symptoms —SYMPTOMS OF EXCITEMENT (MANIA) —*There is excitability of mood* and movement The *mood* is mostly one of jollity rather infectious but likely to become boring or overbearing, occasionally it turns to anger and resentment It is labile tears will flow readily on some trivial occasion to pass into laughter in a twinkling

Thinking is apparently rapid There is flight of ideas with successive words and phrases *loosely connected only by similarities of* sound or chance associations Consequently the patient wanders from the point whether he can *come back to it* depends on the severity of his condition Jokes self praise flighty comment on his surroundings and facile optimism make up the tenor of his exuberant conversation *Nevertheless the number of topics* he touches on in the course of the day is often more limited than if he were in normal health he reverts to a few matters over and over He may criticise himself with cynical bitterness or humour as he criticises others he may talk a lot about bodily disturbances *e g* his varicose veins or his sore throat His mood and expression are consonant *with what he says* He is distractable herein seeming at the mercy of his sensations and of every small detail whether it be inside himself or as is more common connected with things about him *Judgement is impaired*

Delusions are less common than *distortions* and misstatements People are wilfully

called out of their names events misrepresented bodily sensations exaggerated and accusations of ill treatment or persecution irresponsibly preferred and sometimes long persisted in The more confused and excited the patient the more likely to be deluded and even hallucinated Most of the seeming hallucinations are *façons de parler* or illusions sometimes the patient is as it were pretending or acting the part of a hallucinated person

Activity is exaggerated and in severe cases incessant Its object may change from moment to moment but sometimes the main end is kept pertinaciously in view The patient if tactlessly thwarted gets angry sulky or violent He feels very strong and seems untiring He has many schemes of an optimistic cast and in the course of putting them into action may be extravagant inconsiderate or interfering Sexual excesses or drunkenness may occur and bring much harm especially when the patient is a young woman Troubles with the police arise through silly pranks or self confident exploits

Sleep is brief but deep In the early and mild stages the patient looks exceptionally well but after weeks or months of over activity and little sleep he looks exhausted with sordes on his lips, hoarse voice drawn skin and perhaps less total activity but many unfinished little movements Food is welcomed in the mild stages when the activity is great the patient does not give himself time to eat but plays with his food or is continually diverted to something else Sexual desire is at first heightened but potency less

The symptoms vary widely in degree Mild hypomania may be an enviable time of well directed expansive energy unencumbered by some habitual restraints gross mania may be a delirious hallucinatory condition with incoherent talk and little free activity

SYMPTOMS OF DEPRESSION —In the early stages or milder forms the patient finds concentration and recollection difficult he has less interest and pleasure in life he feels that this world is unreal and himself changed he dreads effort or responsibility

The *mood* is one of grief and misery looking in every direction for material to feed on The past supplies peccadilloes or graver lapses what is wretched in the present is dwelt on inordinately the future is foreseen as hopeless ruin Anxiety is mixed with it often in extreme degree Weeping is less common in the extreme forms The patient s expression usually conforms to his affect.

Thinking is more difficult This retardation in thinking shows itself as incapacity to deal quickly and purposively with impersonal topics while brooding on personal matters goes on with a press of inner activity a ceaseless roundabout of painful thought The making of decisions is dodged Conversation may become meagre even monosyllabic though some patients are ever ready to tell their troubles The content of their thought is sombre—the product of ruthlessly unfair examination of their frailties and misfortunes Some criticise themselves remorsefully or with cynical detachment some bewail their losses others abandon themselves to resigned and world shunning despair There are many varieties of misery and melancholia knows them all—as many varieties as can be made from the experiences character and imagination of a human being Consequently they reflect the moral economic or hygienic standards of what is good and bad that are imposed on us by modern society and our particular education

Delusions occur in proportion to the depth of affect they are the extreme form of the doubts or preoccupations just mentioned Patients often fluctuate between uncertainty and conviction about their troubles even during the same day or the same conversation Insight may be good and judgement sound when the affect is not overwhelming The delusions are the product of the depression which is primary they are not its occasion though often adduced as that Most of them concern the future as well as the past anxiety is prominent Wickedness to be visited with damnation secular crime to be punished in this world loss of property that will

mean starvation and beggary for one's family mortal or corrupting diseases—these are the common substance of delusions and are often commingled For example some patients blame themselves for having caught venereal disease which will expose them to the loss of their job and of their hope of salvation exclude them from decent society and do loathsome damage to their bodies no evidence, no argument shakes the erroneous belief The delusions may be grandiose in that the patient affirms himself the chief of sinners no one has ever been as wretched or wicked as he he alone has done the unpardonable sin, or they may be of a minimising sort—nobody cares about him, he is of no account, let him go into a corner to hide people despise him This last belief is often understandably associated with ideas of reference or persecution—people make contemptuous gestures or remarks as he passes they set detectives to watch him they tell each other how bad he is He accepts this almost always as his desert though occasionally there may be overt resentment Apart from this resentment his beliefs derive understandably from his affective state There are however, features that betoken undercurrents at variance with the professed attitude or delusions Thus many depressed patients professing humility are importunate in their demands on those around them

Such hallucinations as occur are in keeping with the patient's affect and are of much the same nature as the delusions though expressed more in perceptual terms People are making derisive remarks his body gives off foul smells food has a different and disagreeable taste—it is often the mode of expression rather than of subjective experience that decides whether these are hallucinations or delusions This is notably the case with bodily preoccupations when for example patients report their food to be stagnating in their belly, their skin dull or fetid their eyes impaired their head empty Much of this depends on depersonalisation in which the body as a whole feels bereft of life and feeling and emotional deprivation or emptiness is translated into bodily experience In mild forms of depression there is no question of delusion or hallucination, and often no recognisable content to the gloom the patient cannot say why he is sad In the more chronic forms a settled and partly justified conviction about ill health, present troubles and the dark future prevails the ideas may be obsessional and partly divorced from the prevailing affect

Activity is limited thus contributing to the retardation' The more severe the depression the less does the patient do unless the concomitant anxiety makes him restless It is possible however, for a patient to be depressed without retardation In typical cases facial expression is rather fixed and movements delayed as though done against resistance more or less complex activities dressing say or writing a letter take unduly long The most extreme form is stupor or lack of all spontaneous activity it is seldom absolute Patients rarely become wholly indifferent to cleanliness in defæcation and micturition

Suicide is the greatest danger in depression Whereas manic patients thoughtlessly do themselves harm or get into a fight but do not try to get hurt depressive patients are often bent upon doing away with themselves The risk is not proportionate to the degree of depression many very retarded and melancholy patients make no attempt while in depersonalised mild cases a fatal outcome is not uncommonly brought about thus There is consequently much risk during the phase of improvement—often more risk then than during the preceding severe retardation Deliberate self mutilation is rare

Sleep is bad—hard to come by light and unrefreshing The *appetite* is bad too food may be constantly refused for this reason Commonly also the patient eats too little because of feelings of fullness and other discomfort in the abdomen or because of delusions about his bowels or his food Mild constipation is common but is often given much exaggerated importance by the patient *The weight* diminishes chiefly but not wholly because of insufficient intake of food Daily fluctuation in the general condition with improvement towards evening is common The skin

may be drv and sallow and in some severe cases pigmented as it is in pellagra Menstruation may lessen or cease sexual desire is much less There may be autonomic disturbance generalised or limited to a single system

Here too there are wide variations, between the mild neurasthenic and the grossly deluded melancholic who craves death There is every gradation between the two extremes and a single patient may during the course of the illness exhibit them all

SYMPTOMS OF ANXIETY —The *mood* ranges from uneasiness to panic stricken terror It may be an abiding or a recurrent state Though chiefly turned to the future as fear must always be it rests on past experience often painful and largely repressed and it reverts to the past to account for the troubles in store Herein as with rationali ation and some other psychological devices there is evident a strong desire to make things understandable in a causal nexus—a tendency to be found not only in patients but also in those who observe them The patient s expression varies with the strength of his fear

Thinking is troubled the disorder showing itself in speech somewhere between frightened dumbness and the voluble talk that seems designed to cover up embarrass ment and disquiet The patient can seldom follow a train of thought for long without a limited number of preoccupations forcing themselves in How far this interferes with daily life or set tasks depends on the amount of anxiety, as does also the impair ment of judgement and insight The content of thoughts is as manifold as in depres sion every normal matter of human concern enters into it. Fears centring strictly on a few special topics *e g* the fear of being run over in the street may be to the fore the fear of insanity is particularly common

Delusions are frequent in the grosser forms which are most strikingly though not exclusively seen in patients of late middle life They may say that their bowels are stopped up and their bodies about to rot their enemies are waiting to tear them to pieces their families will be tortured their names abhorred for ever Hell they are certain awaits their souls though their bodies cannot die time stands still and no redemption is possible There are many delusions less extreme than these mainly hypochondriacal and nihilistic ones *e g* beliefs that employment will be unobtainable or that the patient will be victimised for having had such an illness Hallucinations can occur at the height of fear every sound and sight and smell may be misinterpreted as meaning some pain to come but most of this is illusional colouring of actual percepts Depersonalisation is common with all degrees of anxiety

Activity is much disturbed There may be sudden attacks of panic in which the patient rushes blindly out into the open or aimless wandering ceaseless agitation with movements especially at the small joints—wringing of the hands rubbing the face picking at sores pulling out hair Starting many tasks and finishing none is as characteristic of anxiety as of mania Anxious people are distractable their eyes follow a trivial movement—a fly walking on the window pane—though they only comment on it when some interpretation that chimes with their mood can be fitted their ears are sharp for hints of alarm During an attack of anxiety with strong somatic repercussions activity may be completely interrupted—so called collapse—while the patient terror stricken expects his death alternatively he may run for air or help Very agitated patients may lie or sit in semi stupor with starting eyes and parted lips incapable of speech unless under some strong stimulus

Suicide is uncommon in those with episodic highly somatic attacks of fear and in those with chronic mild hypochondriacal anxiety but not infrequent in the grosser forms and in those mingled with depression

Sleep is bad in the mild forms the patient may be afraid to fall asleep because of his horrifying dreams and the terror into which he suddenly awakes

Sudden highly somatic episodes of anxiety are common the patient feels his

mean starvation and beggary for one s family, mortal or corrupting diseases—these are the common substance of delusions and are often commingled For example, some patients blame themselves for having caught venereal disease which will expose them to the loss of their job and of their hope of salvation exclude them from decent society and do loathsome damage to their bodies no evidence no argument shakes the erroneous belief The delusions may be grandiose in that the patient affirms himself the chief of sinners no one has ever been as wretched or wicked as he he alone has done the unpardonable sin or they may be of a minimising sort—nobody cares about him he is of no account let him go into a corner to hide people despise him This last belief is often understandably associated with ideas of reference or persecution—people make contemptuous gestures or remarks as he passes, they set detectives to watch him they tell each other how bad he is He accepts this almost always as his desert though occasionally there may be overt resentment Apart from this resentment his beliefs derive understandably from his affective state There are however features that betoken undercurrents at variance with the professed attitude or delusions Thus many depressed patients professing humility are importunate in their demands on those around them

Such hallucinations as occur are in keeping with the patient s affect and are of much the same nature as the delusions though expressed more in perceptual terms People are making derisive remarks his body gives off foul smells food has a different and disagreeable taste—it is often the mode of expression rather than of subjective experience that decides whether these are hallucinations or delusions This is notably the case with bodily preoccupations, when for example patients report their food to be stagnating in their belly, their skin dull or fetid their eyes impaired their head empty Much of this depends on depersonalisation in which the body as a whole feels bereft of life and feeling and emotional deprivation or emptiness is translated into bodily experience In mild forms of depression there is no question of delusion or hallucination and often no recognisable content to the gloom the patient cannot say why he is sad In the more chronic forms a settled and partly justified conviction about ill health present troubles and the dark future prevails, the ideas may be obsessional and partly divorced from the prevailing affect

Activity is limited thus contributing to the retardation The more severe the depression the less does the patient do unless the concomitant anxiety makes him restless It is possible however for a patient to be depressed without retardation In typical cases facial expres ion is rather fixed and movements delayed as though done against resistance more or less complex activities dressing say or writing a letter take unduly long The most extreme form is stupor or lack of all spontaneous activity it is seldom absolute Patients rarely become wholly indifferent to cleanliness in defæcation and micturition

Suicide is the greatest danger in depression Whereas manic patients thoughtlessly do themselves harm or get into a fight but do not try to get hurt depressive patients are often bent upon doing away with themselves The risk is not proportionate to the degree of depression many very retarded and melancholy patients make no attempt while in depersonalised mild cases a fatal outcome is not uncommonly brought about thus There is consequently much risk during the phase of improvement—often more risk then than during the preceding severe retardation Deliberate self mutilation is rare

Sleep is bad—hard to come by light and unrefreshing The *appetite* is bad too food may be constantly refused for this reason Commonly also the patient eats too little because of feelings of fullness and other discomfort in the abdomen or because of delusions about his bowels or his food Mild constipation is common but is often given much exaggerated importance by the patient The *weight* diminishes chiefly but not wholly because of insufficient intake of food Daily fluctuation in the general *condition* with improvement towards evening is common The skin

From obsessional disorder the diagnosis may be difficult when there is localised anxiety or depression with sharp content and good insight, so closely alike are the conditions that some authorities have proposed to include obsessional disorder also in the manic depressive group thus disposing of the diagnostic problem It is best however to keep them distinct and to discover in a particular case whether the characteristic subjective rejection of the obsession occurred at its first appearance often the anxious or depressive patient at the beginning has accepted the thought which accords with his affect though later he struggles against it and may disclaim it Genuine obsessions however are common in affective psychoses

Course and Prognosis—The varieties of outcome and sequence are many They depend on the balance between particular intrinsic and extrinsic causal factors in each case and on the extrinsic factors which are brought to bear on it in the form of treatment The more typical the illness the surer the recovery in favourable circumstances

A history of definite affective psychosis in a parent or grandparent points to recovery from the attack but it is unsafe to infer the course of the illness from hereditary data alone A well adapted personality and a pyknic build a history of similar illness followed by complete recovery a fairly sharp and fairly recent onset and precipitation by external troubles which will not be likely to continue are all of them points to the good Advancing years make the prognosis poorer but a first attack of melancholia in late middle life if there be no vascular disease eventually clears up in two thirds of the cases convulsant treatment has further improved the prognosis for this group Bodily changes are often the best indication of coming recovery Improved appetite and regularity of the bowels cessation of anxiety symptoms, clearing of the complexion increase of weight and return of menstruation may be noted, even before any increase of activity and long before any admission of feeling better can be got from the patient

A first attack of excitement or anxiety will seldom be the only one of depression it may Periodic depression and anxiety is less likely to cease in middle life than periodic excitement The occurrence of hallucinations or delusions is in itself of little consequence prognostically A transition from anxiety to depression or mania and from mania to depression or vice versa is commonly gradual Only in predominantly reactive attacks can one surmise *how long the illness will last* or when another attack is to be feared After recovery complete insight into what happened during the illness may not be attained especially by resentful manic patients melancholics who are sensitive and suspicious and agitated patients who feared personal harm

Generalised somatic disturbances *e g* loss of weight especially if acute and brief are of good prognostic import other things being equal The more the somatic preoccupations or symptoms are diffused over a period of time and localised to one system the poorer the prognosis this however does not apply so much to children as to adults Hypochondria and depersonalisation suggest a long illness as do nihilistic delusions (*e g* denying that one s bowels are opened at all) and to a far less extent admixture of hysterical or schizophrenic features The more the psychogenic causes have been obviously operative for a long period the greater the tendency to chronicity In the more chronic forms or after a series of attacks there may be impaired initiative and judgement irresoluteness dullness and social deterioration—none of them conspicuous Puerperal and pregnancy psychoses have a good outlook The milder forms of anxiety and depression if not already chronic respond well to treatment especially to psychotherapy

Death may occur from suicide insufficient food and intercurrent disease especially pneumonia

Treatment—PROPHYLACTIC—Genetic prophylaxis is occasionally possible as when two persons with definite affective disorders marry each other and are advised

heart palpitating his bowels turning over within him he sweats his limbs tremble his mouth is dry, he feels he will fall or collapse or die, he turns pale his pulse rate changes usually becoming more rapid, his blood pressure rises he may want to open his bowels or pass his urine When anxiety is long standing and severe such attacks are rare It is possible for parts of this general affective disturbance to be isolated and to occur with little conscious anxiety, as in muco membranous colitis effort syndrome aerophagy neurotic indigestion enuresis, impotence ejaculatio præcox psychogenic asthma hyperidrosis The factors determining such special emphasis on one or other system are partly physical (some organic defect or innate functional anomaly) and partly psychological In anxiety thyroid enlargement can occur, weight falls off menstruation is irregular or ceases, the deep reflexes are very active

Diagnosis —*Typical* cases are easy to recognise The common errors of diag nosis lie in (1) Missing organic disease (*e g* general paralysis, cerebral arterio sclerosis), or the converse (*e g* mistaking the more expansive manic patient for a general paralytic) (2) Forgetting how mixed the symptoms of mania melancholia and anxiety may be so giving rise to atypical pictures that may be mistaken for schizophrenia if too superficial an examination or too static and rigid a diagnostic criterion be used (3) Forgetting the influences of age general personality and milieu on the content of a patient s mind *e g* his having lived among spiritualists may lead to deceptively fantastic statements (4) Expecting to be able to diagnose solely on *presenting symptoms*, without regard to previous history and constitution the reverse is also to be avoided (5) Expecting diagnosis always to lie between distinct entities which could not possibly be mixed together in the same person, as though hysteria were incompatible with affective psychosis or both of these with schizo phrenia in fact, they often are mingled This is not to make light of diagnosis which gives the psychiatrist much knowledge that he cannot gain from study of the individual case before him

Nothing in the mental state of a patient with affective disorder may enable one to exclude an organic basis such as general paralysis or cerebral arterio sclerosis *This decision must turn on the physical findings* The problem becomes simpler when signs of dementia supervene (see p 1626)

From schizophrenia diagnosis depends on a picture of the whole illness, on the presence of characteristic thought disorder incongruity of affect and bizarreness of behaviour as well as on the previous personality and constitution rather than on any positive features of affective psychosis the remoteness and unconvincing manner of the schizophrenic so hard to describe but almost conclusive when recognised may help Later when complaints have become empty and repetitive to the point of stereotypy and catatonic symptoms mix with the anxiety diagnosis is easier As between schizophrenic and manic excitement the setting in which the excitement occurs is almost more important than the *prima facie* symptoms In young people schizophrenic features may often be found without their being of much significance, in the elderly what seem to be catatonic features may rest on an organic cerebral basis The more easily one can get in touch with the patient enter into his mood and under stand what he says and does the more is it an affective not a schizophrenic disorder The range of benign affective phenomena is wider than a textbook description can convey

There is no need except for administrative purposes to try to diagnose affective psychosis from psychogenic depression cyclothymia anxiety neurosis neurasthenia or involutional melancholia these are only subdivisions of it in which the age of onset reactivity severity or chronicity of the condition is being stressed Periodic recurrence is sometimes made the hallmark of affective psychosis this historically interesting point of view is hard to apply because so many patients have only one definite attack in their lifetime and because periodicity can be striking in other conditions such as obsessional disorder and schizophrenia

other hand some of them soon relapse For manic patients it is on the whole disappointing

Convulsant treatment by the electrical method has superseded chemically induced convulsions It is important that the psychiatrist should not use subconvulsant doses if he can help it The number of fits required varies from patient to patient but it is unwise ever to give a total of more than twenty fits Patients with circulatory or pulmonary disease should only be allowed to have convulsions after the risks have been fully weighed In order to lessen the chance of spinal or other fracture a relaxant is administered usually in conjunction with barbiturate intravenously

For the depressions of middle life convulsant therapy has enough success to justify calling it a specific method of treatment By the electrical method fits lasting less than a minute are induced three times a week not more than ten fits are usually required A relapse may necessitate repetition of the treatment Fragile bones or vertebral deformity may preclude use of the method unless special precautions are taken and the dangers made known to the patient or his responsible relative The treatment should not except in very special circumstances be given as an outpatient procedure It is capable of causing temporary and perhaps permanent cerebral damage though as a rule the forgetfulness or disturbance of consciousness which may follow the fits soon clears up In spite of the simplicity of the actual procedure —hardly more complicated than turning on the wireless—the tiro can do great harm with it by selecting patients who are unsuitable on either mental or physical grounds by giving too many or too few fits and by neglecting methods of preventing fracture and other complications

Patients with severe and long standing agitated depres ion sometimes are much improved by frontal leucotomy the longer they have been ill the less good is the operation likely to do

Prolonged baths—for 8 or 10 hours daily at a constant temperature of 96 to 98 F—have much value in allaying restlessness whether of the manic or the anxious kind especially the former They have the further merit of diminishing angry con tact with other people permitting fairly free movement and lessening dirtiness besides promoting sleep

Drugs are indispensable The fear of habit formation should not prevent hyp notics being given when there is persistent insomnia Barbiturates or paraldehyde often suffice it is well to ring the changes and to diminish the dose without the patient s knowledge For severe anxiety opium (*e g* as papaveretum) and hyoscine may be helpful the risks are obvious Continuous narcosis is valuable but must be used with caution Food must be given in adequate quantity and kind The induction of mild hypoglycæmia by insulin each morning may be helpful in inducing a willingness to take more food Artificial feeding preferably by nasal tube may be necessary because otherwise the patient would die of starvation The presence of acetone in the urine and a falling weight curve are strong indications that nutrition must be attended to promptly A good nurse may sometimes by unusual patience and sense get over an obstinate refusal to take enough food and drink but often nothing prevails against it Apart from hydrotherapy rest in bed fresh air atten tion to the bowels and other measures of general hygiene are desirable

Suicide is of the first importance Prevention of it can be better ensured by close knowledge of the patient and his day to day condition than by mechanical precautions but if he is bent upon it these may be unavoidable It is possible to make them unobtrusive without nullifying them Certain it is that excessive use of bolts and bars can defeat its own ends and excessive supervision aggravate a patient s misery his fears or his resentment Two good rules are (1) to discredit the maxim that those who talk of suicide never commit it and (2) to remember that most suicides are surprises Convalescence from melancholia is a risky time

Occupational therapy is good as soon as the patient can be got to co operate

not to have any children Rules of thumb do not apply in this matter it is wrong to tell a patient he should *marry or not marry*, procreate or not unless one has been able to weigh the dubieties of our genetic knowledge the pedigree of the patient and all his transmissible qualities with an informed and cautious judgement

Individual prophylaxis is not usually practicable until after symptoms have appeared which bring the patient to the doctor social prophylaxis and child guidance may, however have value in staving off or mitigating affective illness especially in those who are temperamentally very responsive to adverse circumstances *e g* in their domestic life their upbringing or their employment No satisfactory evidence is forthcoming that such measures *can forestall the grosser affective disturbances* necessitating mental hospital care which occur in highly predisposed persons In so far as one finds that environmental factors (*e g* heavy responsibility unemployment or sexual frustrations) have been important in provoking an attack advice on these matters may be helpful, it may be practicable by psychological and social treatment during the healthy interval to do much good in this way But some cases in which intrinsic factors seem all powerful, are proof against such measures and in any case it is not easy to persuade the patient when he is well again to put himself for a long time in the doctor s hands

TREATMENT OF THE ACTUAL ILLNESS —It is convenient to consider separately the acute major forms and the minor more chronic cases

For the former *the treatment other than by convulsions is directed to safeguarding* life relieving distress and providing the best conditions for the emotional disturbance to subside the situation is like that in tuberculosis or typhoid fever Exhortations to pull yourself together are as out of place as advice to take a voyage or an argument about the delusions If the attack is sufficiently severe to unfit the patient for ordinary duties treatment at home is probably inadvisable Although in such attacks all argument is futile and active psychotherapy harmful yet the loss of relation between current experience and emotion is never absolute there is virtue in separating the patient from real trouble and distressing associations reassuring him giving him firm kind management The essential combination of these and especially the last is rarely obtainable at home The patients however boisterous or suicidal usually *recognise their need of treatment and are willing to enter hospital* voluntarily They should not transact any business if it can be helped their judgement may be too much disturbed they lay up trouble for themselves Continuous narcosis sometimes curtails an attack it demands experience and care

Convulsant treatment is valuable most of all for involutional conditions least for mania Among involutional patients those with baseless suspicion and resentment respond less well than the self reproachful and agitated *It is still uncertain how* much benefit can be obtained in younger patients with acute affective disorder many of the figures purporting to show that in manic depressives (thus distinguished from involutional melancholics) the recovery rate after convulsant treatment is also high have been compiled from a series of patients the majority of whom had reached later middle life and might therefore have been properly classified as involutional It is moreover difficult to evaluate recovery rates for this purpose in a condition in which recovery is often obtained by other therapeutic methods such as would probably have been employed along with the convulsant treatment Whereas in the depressive conditions of late middle life there can be little doubt about the general superiority of convulsant treatment to any other available method in the affective *disorders of earlier life it is only by the effect* on the duration of the attack and the subsequent frequency and severity of attacks that the efficacy of convulsions can be judged the restricted information available does not give any conclusive general answer though it is evident that on the one hand some young patients have their attacks of depression promptly cut short by this method of treatment whereas previous attacks not treated thus had lasted for many months and on the

other hand some of them soon relapse For manic patients it is on the whole disappointing

Convulsant treatment by the electrical method has superseded chemically induced convulsions It is important that the psychiatrist should not use subconvulsant doses if he can help it The number of fits required varies from patient to patient but it is unwise ever to give a total of more than twenty fits Patients with circulatory or pulmonary disease should only be allowed to have convulsions after the risks have been fully weighed In order to lessen the chance of spinal or other fracture a relaxant is administered usually in conjunction with barbiturate intravenously

For the depressions of middle life convulsant therapy has enough success to justify calling it a specific method of treatment By the electrical method fits lasting less than a minute are induced three times a week not more than ten fits are usually required A relapse may necessitate repetition of the treatment Fragile bones or vertebral deformity may preclude use of the method unless special precautions are taken and the dangers made known to the patient or his responsible relative The treatment should not except in very special circumstances be given as an outpatient procedure It is capable of causing temporary and perhaps permanent cerebral damage though as a rule the forgetfulness or disturbance of consciousness which may follow the fits soon clears up In spite of the simplicity of the actual procedure —hardly more complicated than turning on the wireless—the tiro can do great harm with it by selecting patients who are unsuitable on either mental or physical grounds by giving too many or too few fits and by neglecting methods of preventing fracture and other complications

Patients with severe and long standing agitated depression sometimes are much improved by frontal leucotomy the longer they have been ill the less good is the operation likely to do

Prolonged baths—for 8 or 10 hours daily at a constant temperature of 96 to 98 F—have much value in allaying restlessness whether of the manic or the anxious kind especially the former They have the further merit of diminishing angry con tact with other people permitting fairly free movement and lessening dirtiness besides promoting sleep

Drugs are indispensable The fear of habit formation should not prevent hyp notics being given when there is persistent insomnia Barbiturates or paraldehyde often suffice it is well to ring the changes and to diminish the dose without the patient s knowledge For severe anxiety opium (*e g* as papaveretum) and hyoscine may be helpful the risks are obvious Continuous narcosis is valuable but must be used with caution Food must be given in adequate quantity and kind The induction of mild hypoglycæmia by insulin each morning may be helpful in inducing a willingness to take more food Artificial feeding preferably by nasal tube may be necessary because otherwise the patient would die of starvation The presence of acetone in the urine and a falling weight curve are strong indications that nutrition must be attended to promptly A good nurse may sometimes by unusual patience and sense get over an obstinate refusal to take enough food and drink, but often nothing prevails against it Apart from hydrotherapy rest in bed fresh air atten tion to the bowels and other measures of general hygiene are desirable

Suicide is of the first importance Prevention of it can be better ensured by close knowledge of the patient and his day to day condition than by mechanical precautions but if he is bent upon it these may be unavoidable It is possible to make them unobtrusive without *nullifying them Certain it is that excessive use of bolts and* bars can defeat its own ends and excessive supervision aggravate a patient s misery his fears or his resentment Two good rules are (1) to discredit the maxim that those who talk of suicide never commit it and (2) to remember that most suicides are surprises Convalescence from melancholia is a risky time

Occupational therapy is good as soon as the patient can be got to co operate

but it is not rational treatment to pester a melancholic to encourage the fretful restlessness of the agitated, or to give the manic patient more things to muddle himself with and destroy Still it is often surprising to find how soon under tactful guidance these patients will enter into ordered activity of a more or less simple sort, and how helpful it can be to them During the stage of improvement the same is true of recreations and social activities Patients should not leave hospital till recovery is assured unless it is obvious that the hospital surroundings and the absence from home and work are an actual cause of their persistent anxiety or dejection

To revert to the *milder forms which tend more to become chronic* Here manipulation of the conditions in which the patient lives at home and at work may be conjoined with psychological treatment (individually or in a group) depending on an appraisal of the causes of his illness There is nothing distinctive (though much that takes account of the individual patient s needs) in the psychotherapy and social treatment called for (see pp 1618 1619) danger signals must be recognised as they occur Zeal must give way to the real needs and resources of the patient which are often not appropriate to a drastic or very lengthy treatment Simple measures of enquiry explanation and reassurance, together with small environmental changes may have much effect A fixed régime imposed in detail by the doctor is helpful, this becomes more and more necessary as the affect dwindles in long standing cases Hypomania does not usually respond to causal treatment of any kind it seems to run a largely autonomous course Anxiety may yield very satisfactorily to patient psychotherapy and environmental adjustment

SCHIZOPHRENIA

Definition —The forms of illness under this name are so diverse that many efforts have been made to distribute them so far in vain What is common to them all is a detachment from the world without and a breaking up of normal psychological connections within The personality is not integrated as in normal people thinking emotion and conduct are discrepant and morbid yet there is no impairment *of formal intelligence such as is found* for example, in organic dementia The obsolescent name dementia præcox is not a synonym for schizophrenia but a reminder of its recent history At the end of the last century a large number of patients in mental hospitals were found to have begun their illness before they were 30 and to have passed ultimately into a deteriorated state that looked like dementia their illness was closely studied delimited and called *dementia præcox* When the same clinical picture however came to be found in cases that had not such an outcome or onset, the latter criteria were waived in favour of a descriptive analysis of the actual symptoms and along with this larger conception came the new word schizophrenia which betokened a more psychological approach and a more elastic and generous notion of what might be included Theories of *causation* psychopathology and clinical boundaries are implicit in any view of what schizophrenia' really is consequently it is still possible for two experts to disagree about what should properly be included under this name yet over the diagnosis and prognosis of any particular patient they will attain a measure of agreement and certainty surprising to those who know the condition only from reading or limited experience

Ætiology —INTRINSIC —The intrinsic factors are very important Studies of the incidence in twins and in the members of a family demonstrate a hereditary factor in a majority of cases If one of a monozygotic pair of twins be schizophrenic *the other is also in 76 per cent* of cases whereas the corresponding percentage among dizygotic twins is only 14 The nature of the mode of transmission is still in doubt the most recent observations suggest a single recessive factor which must be inherited from both parents Variations in the manifestation of the disorder may be in part

dependent on a non specific character controlled by a multi factorial genetic mechanism

The constitutional features that betoken an innate predisposition to this illness are more of the psychological than the physical kind The bodily attributes have been said to be an 'asthenic or ectomorph' (weedy and lank) athletic or dysplastic build but since these are found in much the same proportion among healthy people as among schizophrenics and the correlations between habitus and diagnosis are not convincing there is little to be said for them here It is however certain that pyknic build (see p 1646) is uncommon among schizophrenics More significant however are the features of personality commonly called schizoid they are to be found in a large number of cases though not by any means in all The patient is reported to have shown slight peculiarities from his earliest years he has been quiet shy and solitary a ' model child , given more to daydreaming or abstract speculation than to ordinary interests and activity sometimes he has been unduly submissive and sentimentally affectionate or touchy suspicious obstinate and resentful of advice and control A single typical schizoid personality is a *myth* It is moreover to be stressed that a frozen description of the schizoid varieties of personality does not do justice to the true state of affairs characteristic deviations from the conventional norm of behaviour can always be understood better if the patient s way of dealing with his circumstances is viewed historically as a biography of individual tendencies and experiences rather than described as a bundle of traits By paying heed to the development of faulty as well as healthy habits of response the psychiatrist can often see the march of events that led up to the patient s illness and escape too artificial a sundering of inherent tendencies from the external happenings by which these tendencies have been evoked and given shape and substance

EXTRINSIC —The illness sometimes breaks out after childbirth or an acute infection None of the efforts made to inculpate some specific infection have succeeded nor has intoxication in general been found to play any considerable part in the causa tion of schizophrenia The same is true of cerebral trauma There are however many instances of a chronic schizophrenia supervening on an intoxication and of schizophrenic symptoms especially of the catatonic sort appearing in the course of an organic disorder such as G P I or encephalitis lethargica In these the same structural and functional systems must be supposed to have suffered impairment as in the endogenous forms of schizophrenia and it has been particularly urged that in the chronic paranoid conditions that may follow an acute alcoholic psychosis it is really a matter of schizophrenia that happens to be associated with alcoholism if not partly activated or released by it It is further to be remembered that certain intoxications *i e* with mescalin lysergic acid or adrenochrome produce a mental disturbance that is in some respects similar to schizophrenia, and that any chronic *hallucinosis comes in time to look very like a long established schizophrenia probably* because the possibilities for abnormality of any human mind are few the deprivation symptoms almost uniform and our methods of clinical examination imperfect Endo crine disorders especially of the gonads have been held responsible but are more probably manifestations of emotional disturbance findings are not consistent and the relation between endocrine and psychological events still rather obscure

Recent mental stress may sometimes be the starting point of an attack but in a considerable proportion of these cases the reported overwork disappointment in love or other painful experience, is found to have been a product of the already existing illness or the last of a long series of disturbing events No recent experience is ever sufficient to account for the illness without regard to intrinsic causes Nor is any remote experience either No matter how searchingly the patient s life be resurrected and analysed it is scarcely ever possible to discover that anything happened to him which would have led to his adopting a schizophrenic way of shunning daily life unless he had been somehow disposed to it from the beginning although of

course much may have happened to him that has strengthened and fostered the disposition

Among contributory factors, age and sex are noteworthy An onset after the age of 40 is uncommon In three quarters of the cases that later exhibit the characteristic chronic syndrome the illness begins between 15 and 25 *The condition may* become overt in children before puberty Men are more often affected than women—in the proportion of 113 to 100 according to the largest available statistic the matter is dubious however, because of the different standards of diagnosis used

Pathology—PHYSICAL—Histological changes in the brain are not characteristic it is doubtful if they are even frequent A cellular loss in the third and fifth layers of the cortex with lipoid accumulation has been found but *it occurs in many* other conditions Swelling of the oligodendroglia has been described in brain tissue obtained at biopsy Many claims about cerebral pathology and the chemical and physiological changes in schizophrenia have now been discredited *so that all findings* in this difficult field have come to be matters of suspicion Variations in the same individual may be wide Investigations have purported to show a disturbance of the acid base equilibrium towards the acid side with a diminished excitability of the respiratory centre to carbon dioxide lowered rate of oxygen consumption polyuria diminished gastro intestinal motility poor response to epinephrine, insulin and dinitrophenol, and to vestibular stimulation by cold water or rotation abnormal heat regulation, abnormally variable sugar creatine and non protein nitrogen content of the blood anomalous capillaries decrease or sluggishness of total blood volume, and slowing of the arm to carotid circulation time These findings indicative of a defect in adaptive capacity have not so far been controverted they represent disorders of metabolism and regulation which may be partly a concomitant of the characteristic mental disorder and partly an effect of it *i e* they may be essential physical disturbances in the illness, or may be secondary to the abnormal often inert life the patients have led since they became ill thus evidence of hepatic dysfunction in catatonic patients is of nutritional origin and may be corrected by changing to a suitable diet

Some inferences have been drawn from the similarity of catatonia to the extra pyramidal syndrome that can be produced in animals by bulbocapnine the argument from analogy cannot be pushed further than to say that certain functional systems are available in the brain disorders of which are sometimes evident in schizophrenia as they also may be in poisoning or in encephalitis lethargica G P I and other diseases

Very significant are the well attested metabolic findings in the rather rare cases of cyclical catatonia In these the nitrogen balance varies periodically with alternating phases of retention and over excretion corresponding to the mental change from excitement to stupor or vice versa By means of thyroxine a thorough *emptying* of the patient s nitrogen store can be brought about and subsequent nitrogen retention prevented thus leading to clinical improvement The correlation between metabolic happenings and clinical condition in these patients is *now established*

PSYCHOLOGICAL—The large and inconclusive literature on the psychopathology of schizophrenia derives from

(1) Minute description of the phenomena observed and abstraction from them of general principles of disordered function
(2) Experimental study using projective sorting reasoning and other tests as far as possible under controlled conditions
(3) Studies of artificial hallucinoses (*e g* mescalin intoxication) and parallel experiences
(4) Comparative study of animals *children poets primitive* people etc.
(5) Intuitive or speculative interpretation

It will be obvious that these methods overlap and that they differ widely in

acceptability and usefulness The findings of almost all can sound plausible when stated in general terms discrepant or abstruse when stated in detail Their exposition touches on the most intricate problems of normal and morbid psychology and therefore is highly technical and unsuitable here A working hypothesis for clinical purposes is that in schizophrenia there are inherent faulty dispositions whose manifestation depends in severity and persistence on upbringing and other external circumstances It is characterised by among other things a perversion and failure of synthesis so that there is an inco ordination intrapsychic ataxia as it were a splitting up of the mental life which justifies the name Schizophrenia The whole psychic life of the patient cognitive emotional and conative may be changed in a way that is alien to normal understanding We can observe the change but to enter into it or describe it adequately in terms of our own experience is far more difficult than if we try to do this for depression manic excitement hysteria or obsessions It shows itself also as a turning away from the contacts and realities of daily life a preference for what the mind can supply from its own stores however morbidly rather than for the current experience that the outer world affords

Symptoms —Schizophrenia may be regarded for clinical purposes as a form of maladaptation in which there are characteristic defects of inner harmony and consistency in behaviour thought and emotion These are rarely seen in childhood but from puberty onwards they may appear in varied combinations (often in persons who for years have been introspective and unsociable) There is discrepancy between mood and utterance disturbance of conduct (briefly summed up as catatonic or hebephrenic) self absorption and incapacity for sustained thinking along normal lines A guarded or artificial demeanour may conceal these essential features whereas they may be conspicuous in a florid or deteriorated case Hallucinations and delusions may fill out the picture affective or other morbid types of reaction may complicate it

The onset is not always abrupt There is often a long history of preliminary symptoms in which it is arbitrary to decide where personality has merged into illness Complaints of headache weakness anxiety attacks loss of appetite and dysmenorrhœa may have accompanied slight oddities of behaviour such as rudeness or apparent absence of mind and indecision The patient may have felt an alarming change in himself in his capacity to think and feel normally and been notably depressed and anxious Ideas of persecution or of exaltation may occasionally escape him or he may have become stilted in his talk and shown other affectations and mannerisms The more gradual the onset—and in many cases it has spread over many years—the more unlikely is it that it will have been recognised as morbid

The commonest or basic symptoms are (1) Disorder of thinking (2) Emotional incongruity (3) Hallucinations (4) Disturbed impulses or conduct From these can be derived most of the other symptoms such as delusions feelings of influence autism catatonic phenomena anomalies of speech negativism and the rest

The *disorder of thinking* is a characteristic and central feature The patient cannot command the whole range of an act of consecutive thought he misses the point fastens on details and brings in irrelevant associations which are correct in themselves but which divert him from the main end of his original process of thought consequently his thinking is incoherent rambling and jumbled He brings together the most far fetched topics so that the connections are sometimes so superficial as to be empty of meaning and at another time profoundly influenced by symbolism and highly individual values The usual logical sequences are ignored cause and effect are interchanged temporal spatial verbal and accidental relationships are unduly turned from abstract to concrete treated as grounds of identity played with or flouted Things linked only by analogy and chance association are taken to be the same The condensation of several conceptions in one or transference of a set of attributes to some inappropriate object may become a matter of course so that only the closest knowledge of the patient and his surroundings will enable the psychiatrist

to follow his meaning It is not necessary however that such extreme *incoherence* be evident in the patient s talk he may not show any at all when speaking or may suddenly obtrude a startling lapse from normal ways of thought which he then ignores justifies or explains away Inconsistent thoughts can be present together in a way impossible for normal people and the same object or notion can appear to him in several interchangeable guises each of which would normally exclude the others The patient himself is often aware of his disordered thinking and may describe it he feels his thoughts are suddenly taken out of his mind other thoughts foreign to him are put into his head, his mind is not his own his thinking is suddenly interrupted, some external power controls it

The thought disorder is illustrated by the following characteristic remarks of patients There were bats and bees coming through the window, of course that was because my brother in law kept teasing me He said I had bees in my bonnet' 'If I should return during my absence, keep me here until I come back' I have a lot of forced thoughts My thoughts are all drawn out words they ought to be pin pricks There is an unnatural stoppage in my thoughts, too I have heard voices say, He is conscious of his life To get my feeling back to normal I feel like changing motor cars into battleships to be superior to them

This disorder may only be demonstrable when the patient gets on the topic of his delusions in other matters he may seem quite sensible It is not essentially different from what normal people experience during states of altered consciousness *e g* in dreams or when falling asleep, the schizophrenic however has it with clear consciousness so that a listener often feels that the patient is making fun of him in giving such transparently absurd answers with an air of knowing exactly what he is about A chronic well preserved schizophrenic has been known to make his living as a comedian the audience much enjoying the allusive, half comprehended nonsense with its background of innuendo and symbolism Autism *i e* immersion in his own fantasies and preoccupations may account for much of the oddity and detachment the patient shows it accounts also in part for his negativism , in that he resents any stimulus that interferes with his daydreams

Delusions arise mainly out of the thought disorder They are often bizarre they may occur to the patient with a suddenness of conviction that puts them beyond all argument and they are egocentric in that they commonly bring indifferent happenings or people into a special relationship with the patient—*e g* he suddenly knows that when his cousin yesterday said he had been reading about Napoleon s divorce of Josephine it was a subtle way of telling the patient that his wife was committing adultery with this cousin whose name is Joseph The delusional ideas may not be firm conviction but fleeting notions readily given up and based upon some casual instance of the thought disorder, sometimes they are schizophrenic ways of saying something commonplace—*e g* the patient declares his wife has poisoned him but when he is further questioned says airily that he means she gives him ill cooked food which is bad for his digestion

Fixed delusions are however common and are usually of a paranoid complexion they may develop out of more or less ephemeral ideas of reference They are often intermixed with hallucinations The patient gets into a state of mind in which he feels there is meaning in everything something is going on behind the scenes he is perplexed by all this and mystified it has to do with him in some uncanny way Presently, he begins to see through it all sometimes he gives it some religious or cosmic significance, especially if he has much anxiety as well—the Last Judgement is at hand he is to be responsible for the regeneration of the whole world The delusions are not always enacted on so grand a stage there may be homely fancies about neighbours who whisper and sneer, or about some bogy like the Jesuits or the Jews or the C I D Often the patient complains that people work on his mind hypnotise him influence him for his own good set about to drive him mad or ruin

him Delusions of grandeur may be linked up with these paranoid ones (*e g* he is being persecuted because he is the Messiah) and may be likewise pedestrian or lofty according to the patient s previous education and interests the severity of his dis order the copiousness of his fancy and the amount of normal mental function still in evidence Here as elsewhere in psychiatry the symptoms are a mixed outcome of impaired or perverted function on the one hand, and of normal function on the other the latter either reacting to and modifying the disorder or obtaining freer play through it If for example a patient feels his thoughts being controlled by some external influence and he has queer tinglings in his body his conviction that he is being hypnotised and that someone is playing an electrical instrument on to him must be regarded as a normal attempt to find the cause of an almost inexplicable happening The delusions are sometimes about past events which are falsified retrospectively *e g* the patient relates details of his having been a changeling or a predestined hero Delusions about bodily transformation or disease are frequent, and may be complicated and bizarre

Patients often do not act in accordance with their delusional beliefs especially when these are fleeting or chronic they may for example be friendly towards a nurse whom they believe to be persecuting them cruelly But this is on the whole unusual in the early or acute stages of the illness a patient will then act on his beliefs violently or in terror he may go to the police or be driven to suicide

Constantly the matter of a patient s delusions will be found to be intimately dependent on his experiences his emotional attachments and sufferings his struggles and frustrations it is impossible however by any such analysis and derivation of his delusions to account for the fact of their occurrence *i e* for the patient s choice of this way of dealing with the experiences in question The same is true of the general thought disorder *e g* interruption or blocking of the train of thought may take place only when some emotionally weighted topic some complex is touched on This accounts for the place where blocking occurs but not for the blocking itself that like the other fundamental disturbances of function in schizophrenia eludes a wholly psychological explanation

Intellectual defect does not occur though the patient may find it difficult to form concepts necessary for abstract thinking There is usually no clouding of conscious ness Intellectual laziness or evasion is often conspicuous the patient may repeat questions in a musing way or profess ignorance Orientation and memory are not as a rule diffusely impaired though hallucinations delusions and lack of interest may interfere with them and consciousness may be disturbed in stupor or excite ment Many a patient who has long borne the appearance of gross dementia will suddenly show that his intelligence is still a sharp instrument drugs *e g* sodium amytal or insulin and intercurrent disease or shock can thus dramatically reveal how little ground there is for calling this illness a dementia Schizophrenics often do the unexpected Amnesias and deliria when they occur in schizophrenia may be hysterical obsessional and hysterical symptoms like anxiety and depression are compatible with schizophrenia and are often an intimate component of the illness

The speech and writing of the schizophrenic betray the extent of his thought disorder Stiffness pedantry fantastic euphuisms words of his own coining queer symbols and grammar stereotyped repetition and infantile twists like speaking of himself always in the third person may be conspicuous features of the patient s use of language There may of course on the other hand be little or nothing outwardly amiss in his conversation and writings In florid or chronic cases the patient may talk in an unnatural voice or without any modulation Writing may be set forth as though it were painting and the converse in subject and matter the patient s in sanity may be patent but his treatment of his matter however odd, is seldom odder than some forms of art and it cannot be called typical of the illness These anomalies of symbolical representation are as open to psychological explanation as are the

delusions mentioned above the neologisms for example can be analysed up to a point and these phenomena have enriched our knowledge of the psychopathology of schizophrenia

The *emotional incongruity* is the chief, but not the only, sign of disturbed affect Often the patient himself notices in the beginning of his illness that he is less moved by habitual affection or even feels hatred towards a parent he has loved The strongest and rarest of human passions are not infrequent in this illness ecstasy mystic communion despair, horror agony of death limitless abandon apotheosis salvation are approximate names for these exceptional states that are probably indescribable in the current language of normal people Apart from these and much the commonest of the affective changes is apparent emotional shallowness the patient receives moving news without any sign of being touched by it or his response is perfunctory he smiles or looks bored when talking of a recent tragedy in his own family This shallowness and incongruity of affect is however not to be taken at face value What the patient says and what he means with his words, may be very different so may what we say be very different from the meaning the patient attaches to it *It is unsafe to assume that the patient s words have reference to what is mainly* going on in his mind at the moment or that his outward expression is a trustworthy index of his emotional state Violent emotional outbursts—of anxiety rage love misery—can certainly occur in a patient who has lately seemed empty of all affect The schizophrenic patient is undoubtedly different from normal people in his emotions but not in so negative a way as his seeming apathy and lack of affective rapport would suggest His attitude towards the same person may change quickly in accordance *with conflicting or opposite tendencies in himself*, *this ambivalence is often* understandable in the light of his earlier history Sometimes the illness leads to a blunting of ordinary reserve a lack of reticence, or a levelling down of the gravest matters so that frivolous or cynical indifference and imperturbability are signs of the patient s morbid condition

Hallucinations are not so frequent as superficial examination of patients might suggest many of the patient s assertions about queer sights and sounds are not the *expression of vivid perceptions but of passing fantasies imagined more* plastically than is normal this is particularly true of many of the so called visual hallucinations or of cases where the unreal perceptions occur in several senses together Hallucinations are nevertheless extremely common and persistent in schizophrenia auditory ones occur most often diffuse somatic ones not infrequently those of smell taste and sight more rarely

The voices are sometimes so closely linked with the thought disorder that it is difficult to tell whether the patient is relating what he has heard or what he has thought He may show the intermediate stages between the two declaring that people repeat his thoughts or that everything that passes through his mind is spoken aloud inside his head his actions are described publicly he cannot go to the lavatory without shameless comments What the voices say may be abuse or encouragement trivial repetition or threats and commands this content can usually be accounted for by the psychiatrist when he knows the patient and his history well The voices may come from strange places *e g* from inside the patient s own chest or abdomen and are then often accompanied by curious somatic hallucinations indicative of morbid attitudes both physiogenic and psychogenic towards parts of the body The latter often occur independently Queer sexual feelings or distortions and impossible growth of *various organs may be reported* They are usually bound up as any schizophrenic symptom is likely to be with delusional and emotional components which are partly derived from the patient s experiences and psychological development The visual disturbance like the gustatory is more often illusional than hallucinatory *e g* people s faces *look fiendish or artificial or transfigured*

The *actions and bearing* of the patient are often characteristic. Abruptness or

lack of grace in movement may be seen early it can be indistinguishable from the fidgety self conscious hobbledehoy stage of adolescence The patient may pull faces at himself in the mirror or may be unaware of his grimaces Asymmetrical move ments of expression twitchings mannerisms queer rituals and tic like gestures are to be met with The meaning of the patient s movements can usually be worked out but after they have been present for long their sharpness is rubbed off, as it were and the empty stereotyped movement at last gives little clue to what was once a significant emblem of experience and feeling The movements often seem to become automatic, like the ' verbigeration of empty phrases in the patient s speech Nega tivism talking and acting beside the point and bizarre escapades may be seen at any stage of the illness

There may be a suspension of movement or the reverse akinesis or hyperkinesis Both may occur in the same patient who may lie for weeks or months in a catatonic stupor from which he suddenly emerges into swift action He may carry out some impulsive action and then promptly return to bed and stupor or he may become wildly excited and imperil his life by his blind and raving activity During catatonic stupor patients may adopt strange postures *e g* holding their head off the pillow all day pursing their lips They may be indifferent to cleanliness about fæces and urine or actively dirty in this regard Waxy flexibility is rare but many patients are auto matically obedient so that they keep up an imposed posture

The variety of schizophrenic anomalies of conduct is too great to be described here They must not be assessed absolutely but always in relation to the setting in which they occur Then they have meaning in the individual case and are not merely so many examples of ambivalence or mutism or negativism ' It is however true in this matter also that understanding the content of an anomaly does not make its occurrence likewise understandable Much of the schizophrenic s conduct is so close to certain disorders of movement in organic disease of the central nervous system and its connections that somatic mechanisms may be assumed to have suffered damage in this condition There are three main things to be done with any schizophrenic symptom (1) to search out its psychological origins and its meaning for the patient in his present situation (2) to link it up with the other functional disorders that he shows and (3) to consider its background of physical structure and function It is not always practicable to attempt all three nor is it as yet possible to do them well but none can be ignored without detriment to a full analysis

Often the most significant yet intangible effect of the illness is upon the patient s *personality* After florid symptoms have died away or when there are no definite symptoms at all a change in the patient s ways is remarked by his intimates Not only is he outwardly different—more peculiar less understandable and predict able rather shut in upon himself remote with queer values and impulses—but in many cases he is also aware of this change and may complain of an inner perversion of himself a loss of that unity which we take for granted when we say I or me Insight in schizophrenia in this respect and more generally too may be penetrating and just as many self descriptions attest There may also be varying degrees of impairment up to gross lack of insight

None of the *bodily symptoms* are characteristic of this illness though many occur Besides the somatic complaints and preoccupations already mentioned patients especially if young show vegetative anomalies Thus vasomotor disturbance may take the form of cold bluish extremities exanthems or œdema Seborrhœa is common Abnormal growth of hair occasionally occurs in women Loss of weight in the acute stages and fatness in the chronic condition interruption or irregularity of menstruation and fluctuations of temperature may also be observed especially in catatonic cases of the schizophrenic states stupor is the richest in demonstrable bodily changes Fleeting neurological signs *e g* pupillary anomalies may be found

delusions mentioned above the neologisms for example can be analysed up to a point, and these phenomena have enriched our knowledge of the psychopathology of schizophrenia

The *emotional incongruity* is the chief but not the only, sign of disturbed affect Often the patient himself notices in the beginning of his illness that he is less moved by habitual affection or even feels hatred towards a parent he has loved The strongest and rarest of human passions are not infrequent in this illness ecstasy mystic com munion, despair horror agony of death limitless abandon apotheosis salvation are approximate names for these exceptional states that are probably indescribable in the current language of normal people Apart from these and much the com monest of the affective changes is apparent emotional shallowness the patient receives moving news without any sign of being touched by it or his response is perfunctory he smiles or looks bored when talking of a recent tragedy in his own family This shallowness and incongruity of affect is however not to be taken at face value What the patient says and what he means with his words, may be very different so may what we say be very different from the meaning the patient attaches to it It is unsafe to assume that the patient s words have reference to what is mainly going on in his mind at the moment or that his outward expression is a trustworthy *index of his emotional state Violent emotional outbursts—of anxiety rage love* misery—can certainly occur in a patient who has lately seemed empty of all affect The schizophrenic patient is undoubtedly different from normal people in his emo tions but not in so negative a way as his seeming apathy and lack of affective rapport would suggest His attitude towards the same person may change quickly in accord ance with conflicting or opposite tendencies in himself this ambivalence is often understandable in the light of his earlier history Sometimes the illness leads to a blunting of ordinary reserve a lack of reticence or a levelling down of the gravest matters so that frivolous or cynical indifference and imperturbability are signs of the patient s morbid condition

Hallucinations are not so frequent as superficial examination of patients might suggest *many of the patient s assertions about queer sights and sounds are not* the expression of vivid perceptions but of passing fantasies imagined more plastically than is normal this is particularly true of many of the so called visual hallucinations or of cases where the unreal perceptions occur in several senses together Hallucina tions are nevertheless extremely common and persistent in schizophrenia auditory ones occur most often diffuse somatic ones not infrequently, those of smell taste and sight more rarely

The voices are sometimes so closely linked with the thought disorder that it is difficult to tell whether the patient is relating what he has heard or what he has thought He may show the intermediate stages between the two declaring that people repeat his thoughts or that everything that passes through his mind is spoken *aloud inside his head his actions* are described publicly, he cannot go to the lavatory without shameless comments What the voices say may be abuse or *encouragement* trivial repetition or threats and commands this content can usually be accounted for by the psychiatrist when he knows the patient and his history well The voices may come from strange places *e g* from inside the patient s own chest or abdomen and are then often accompanied by curious somatic hallucinations indicative of morbid attitudes both physiogenic and psychogenic towards parts of the body The latter often occur independently Queer sexual feelings or distortions and impossible growth of various organs may be reported They are usually bound up as any schizophrenic symptom is likely to be with delusional and emotional com ponents which are partly derived from the patient s experiences and psychological development The visual disturbance like the gustatory is more often illusional than hallucinatory *e g* people s faces look fiendish or artificial or *transfigured*

The *actions and bearing* of the patient are often characteristic Abruptness or

that the speech and acts of the latter are intelligible as expressing a general affect and are conformable to the situation in some measure the onset and cessation are not so abrupt as in catatonic excitement and there are usually characteristic features which make the distinction easy Melancholia becomes suspect when delusions are repeated without the appropriate effect, and there is a readiness to project responsibility for the illness to complain of external influence The inertia of the depressive is not so complete as that of catatonic stupor, nor so likely to be abruptly broken through States of severe agitation are not always easy to distinguish from schizophrenic excitement, but a more frequent problem is that of deciding whether some bodily fear or conviction of disease is schizophrenic or not Whether in regard to a preoccupation or a delusion the chief point to consider is the appropriateness of the affect to the alleged hypochondriacal notion, the more bizarre the bodily change described, the more likely to be schizophrenic Depersonalisation is sometimes at the bottom of these somatic complaints what is significant is not the depersonalisation but the way it is elaborated and regarded by the patient

Hysteria can offer great difficulties largely because hysterical mechanisms are so often operative in schizophrenia Plain motor or sensory disturbances commonly give less trouble than hysterical dissociation stupor and pseudo dementia The *previous history the relationship of the outburst to a particular set of happenings* the behaviour in the intervals the demands upon the attention or response of by-standers must be taken into account The mistakes and oddities of the hysterical pseudo dement may be theatrical in accordance with his ignorant notion of what insanity is like the deliriously dissociated hysteric does not identify correctly the people around him as the schizophrenic usually does even when in a dream like state the hysteric who is acting some imagined scene does so without discrepancies or gross interpolations whereas the schizophrenic is seldom so consecutive and persistent The degree to which the patient is being influenced by his immediate surroundings is however the chief guide apart from definite schizophrenic features

Obsessional states offer difficulty when the patient is in doubt as to whether his alien thought or impulse comes from within his own mind or is imposed upon him If he shows indifference as to the occurrence and content of the compulsive ideas it is suggestive of schizophrenia but careful examination of the development of the symptom and the patient s attitude towards it permits a clear diagnosis in most cases Complicated rituals odd obsessions and chronicity make an obsessional illness look very like schizophrenia as does intoxication of an obsessional patient by bromides Obsessions may develop into schizophrenic symptoms (see p 1679)

Prognosis —Schizophrenia is always a serious condition Though some recover the tendency of this morbid change is to do permanent damage to psychic life In the individual case however pessimism is not justified It is certainly never possible in the early stages of the illness to be certain that recovery is out of the question

Heredity is a poor guide to the prognosis except in the rare cases in which an identical twin of the patient has for some years had a schizophrenic illness or in which one parent is schizophrenic and the other has schizophrenic relatives even then it is difficult to prognosticate with assurance regarding the present attack If one parent has had an affective illness the prospects of recovery are brighter but this can better be assessed from the patient s own bodily and mental constitution If he is of pyknic build the outlook is much better Similarly the patient who has for years tended more and more to withdraw from his surroundings to be careless of social requirements to lie late and live alone given up to day dreaming and eccentricity—such a one should he become overtly schizophrenic has a poorer chance of doing well than the active suspicious and impulsive man or the self conscious introspective worrier who similarly falls ill A narrow and rigid previous personality makes deterioration more likely than if there had been wide interests and possibilities of adaptation

In states of acute excitement attacks of unconsciousness may occur but epileptic seizures are very rare

VARIETIES —*There are three main forms*—catatonic (with acute outbursts) hebephrenic and simple (early onset chronic course), paranoid (fairly late onset delusional) They are not exclusive categories and it is usually profitless to try and apportion a doubtful case to *one or the other* They do not correlate closely enough with outcome or effective form of treatment to be of much use clinically

In *hebephrenia*, the least common variety delusions and hallucinations are inconsiderable but *abnormal conduct is to the fore* the patient may be silly and mischievous abruptly eccentric or inert and without initiative The illness may progress without acute episodes (dementia simplex) or be interrupted by phases of excitement or *obvious insanity which subside, leaving* the patient worse than before In *catatonia*, the most favourable variety the symptoms are plain even to the layman akinetic or hyperkinetic states may appear and subside quickly, sometimes for good or *for several years There are usually*, also, characteristic disorders of thought and emotion which may clear up when the stupor or the excitement does In the *paranoid* form, generally rather late and insidious in its development but less damaging to the *personality than the hebephrenic, partial systematisation of the* delusions is common in the earlier stages but may be later swallowed up in the general thought disorder and deterioration (dementia paranoides ') The more bizarre the delusions the *more likely is affective emptiness to replace gradually the initial* resentment and distress but sometimes the patient passes into a chronic paranoid state obviously schizophrenic to the psychiatrist but compatible with ordinary life outside an hospital Hallucinations and luxuriant delusions may however be conspicuous in the paranoid form (paraphrenia and dementia phantastica)

Diagnosis —The chronic and advanced cases— typical dementia præcox — *that abound in mental hospitals are easy to diagnose but early or inconspicuous* cases often extremely difficult The chief positive points to look for are characteristic thought disorder a qualitative change of affect and other evidence of intrapsychic *ataxia as well as feelings of being under external influence* Catatonic symptoms are of limited diagnostic value because of their frequency in organic and symptomatic psychoses More important than any single feature is the impression of the cases as a whole the development away from normal interest and response to the real world and the establishment instead of autistic self satisfactions so that the patient s personality is twisted awry as it were and withdrawn from easy contacts

It is unsafe to lay much weight on the diagnostic help afforded by projective and other psychological tests The intuitive element in the interpretation of Rorschach and other findings of this kind is greater than is consistent with a reliable diagnostic procedure The psychological data may suggest schizophrenia but should not be the decisive factor

From organic syndromes—syphilis of the central nervous system alcoholic psychoses disease of the cerebral vessels encephalitis lethargica etc —*the differentiation* turns on the physical findings more than on the mental state a schizophrenic syndrome may appear in an organic condition because the brain as Kraepelin said is like an organ whose stops give out the same sound whoever works them Often it is not a matter of deciding whether the syndrome is organic or schizophrenic *but* whether being schizophrenic it has a discoverable somatic basis or not Alcoholic delusional states are an instance of the complicated relationship that may be found (see pp 1638 1639) If after consciousness has become clear *again the other* phenomena of toxic confusional psychosis persist then schizophrenia is the more probable diagnosis

Diagnosis of schizophrenia *from an affective syndrome is* difficult because both are often combined in the same patient. Some of the significant points have already been referred to (see p 1652) Catatonic excitement differs from mania in

into ordinary life as soon as possible provided conditions there are not too adverse for him or he too abnormal to cope with them

Treatment in a psychiatric clinic or mental hospital is usually necessary at some stage of the disorder and must be decided chiefly by the severity and social risks at the time For the large number who become permanently in need of institutional care much of the deterioration formerly customary may be averted by the energetic use of occupational therapy and recreation which make the patient s life less sterile The term total push has been applied to a programme having this object, and attaining its social end in proportion to its vigour in using all available means of stimulating and encouraging the individual patient

There are few conceivable ways of altering a human being that have not been tried in this illness Many of them have been those believed to be efficacious in other illnesses some have been intended to shock the patient somehow Of the former may be mentioned thyroid and other endocrine preparations (in large doses) transplantation of gonads removal of supposed septic foci induction of fever by malaria etc injection of human serum, manganese salts production of aseptic meningitis hypothermia and continuous narcosis Of the latter *i e* shock methods many of the procedures of a bygone time are examples the whirling chair, precipita tion from a height, immersion in ice cold water and so forth The most recent methods which entail a profound disturbance are those which use insulin or a con vulsant (see p 1621) The convulsant method has been of value in some acute stupors and conditions in which, along with the schizophrenia there is a considerable affective admixture

The value of insulin treatment is variously assessed some believe that it should be given to every schizophrenic as soon as his condition is recognised others that it benefits those who would get well with other forms of treatment if administered with equal zeal The former say that it shortens the duration of illness and increases the number of recoveries the latter insist that this improvement is seen to be largely spurious if a follow up enquiry is made into the later course of the patients lives That such extreme views can be held by responsible observers relying on large series of cases is due not only to their prejudice and temperament but to the difficulties of judging therapeutic success in an illness which is sometimes difficult to diagnose with certainty in its early stages is often accompanied by another more benign mental illness and has anything but a uniform prognosis moreover it was believed to be hopeless by many psychiatrists in pre insulin days so that they did not try to treat it by methods then available which would have yielded full permanent recovery in a quarter of the cases if selected on the same basis as is now customary for insulin treatment It was the general experience before the advent of insulin that a third of the schizophrenic patients who were admitted to an active psychiatric hospital within a year of the onset of their illness got better with general treatment and remained capable of life outside a hospital mass figures from a heterogeneous collection of psychiatric hospitals showed less satisfactory results This partly accounts for the discrepancy between those who report remarkable improvement in the pro portion of schizophrenics who recover now that insulin has been used for their treatment and others who cannot discover any statistically recognisable difference in efficacy between conservative treatment and the insulin method under comparable conditions of case selection and management An additional cause of discrepancy in results lies in the different methods of administering insulin treatment Some aim at giving the lowest dose of insulin that will produce coma others prefer the highest dose that can be given without endangering the patient s life some let the comas continue for 3 or 4 hours others terminate them earlier and there are even advocates of comas protracted up to 15 hours for patients unresponsive to milder measures, hypoglycæmic convulsions are regarded by some as therapeutically valuable by others as harmful Insulin and convulsant treatment have demonstrated beyond dispute

The more abrupt and stormy the onset, the better the outlook This is one of the most reliable guides When the onset has followed upon a recent painful experience and the content of the patient s talk and his behaviour refer to this or when a physical damage appears to have provoked the symptoms (*e g* influenza or head injury), the outlook is rather better than when the provoking factors are obscure but this is by no means always the case If the attack occurs during puberty or adolescence prognosis must be cautious because of the difficulty of distinguishing between the transient upsets of this period of adjustment and the progressive schizophrenia that may then show itself plainly The earlier history is of great help

The nature of the symptoms is not a safe guide Very severe departures from normality may clear up yet an outwardly mild condition be of grave omen Symptoms such as stereotypies of movement and speech which indicate that the illness has been going on a long time and that there is a general narrowing and fixity are grave as are also hebephrenia and a long drawn-out stupor with negativism impulsive violence and vasomotor changes The more manic or depressive features the better Previous attacks with an interval of normality between them, are prognostically favourable If the patient first falls ill after 30 he will scarcely go downhill in the tragic way young people sometimes do He may develop fixed delusions which are often rigid and encapsulated, so to speak, and therefore he may be able to return to ordinary life, with reservations or it may be that his morbid beliefs absorb all his mental powers and compel institutional life The more the psychiatrist can discover healthy modes of response in the illness itself as well as in the previous personality the happier the outlook Many patients, after an attack do not return to work but have narrower interests and less spontaneity than before, they are more easily tired and may be hypochondriac or show other symptoms thought to be neurotic " Such patients have sometimes made a poorer recovery than others who return to work and can meet most social demands, though careful enquiry reveals definitely schizophrenic sequelæ in their thinking and emotions

The simplest rule is that an abrupt onset of the illness an adequate cause for its occurrence and a well adapted non schizoid personality are the criteria of good prognosis Sensible early treatment may avert disaster

Treatment —PROPHYLACTIC —This, whether eugenic or individual, is limited and uncertain Even if effective, it can reach only a minority at present, and its effectiveness is a matter of faith Probably child guidance and other measures of mental hygiene do good in averting potential schizophrenia but no one can be sure of this Such treatment aims at diverting the child into social activities and keeping him out of situations in which he will be mortified or otherwise troubled emotionally However wordily or abstrusely the prophylactic treatment be described, it is essentially a matter of trying to make an unusual child into an average one or changing his surroundings to suit him

TREATMENT OF THE ACTUAL ILLNESS —There is no one treatment of the disorder that has manifest superiority over any other Insulin has striking results in some early cases but is neither a specific nor a panacea Painstaking attempts at readjustment of the patient s outlook and behaviour by means of suitable psychotherapy, occupation games etc are the most systematic and rational ways of making a permanent change for the better The co operation of the patient is here necessary and also the help of a social worker desirable who may do much to modify and arrange the patient s circumstances in the interests of his mental health *e g* getting him suitable occupation and schooling his relatives in a sensible attitude towards him Such treatment is not practicable for those acutely ill but for the mild the convalescent or the imperfectly recovered case it is of great value By means of it many patients can be discharged from hospital before they have settled into apathy or become unresponsive to the claims of the external world it is better not to keep a schizophrenic patient in hospital waiting for complete recovery but to get him back

general trend of the illness and their prognosis and treatment must be assessed accordingly

Besides the paranoid beliefs and attitude referred to in previous sections there are a number of instances of this unhealthy relationship between the patient and his surroundings which may be mild in their outward form easily understandable in the light of the patient s history and fairly responsive to treatment Some deaf people become distrustful misinterpreting what they cannot hear plainly and construing it into a jeer or an insult Sensitive and shy people are often troubled by doubts and shame as to their physical or moral worth and by projection attribute to others the dislike or contempt they do not acknowledge in themselves This occurs in youths who masturbate and suppose others to remark it and in old maids who believe men to be pursuing them but there are many varieties of shame and desire besides the sexual which lead to such ideas of reference or persecution The development of paranoid reactions of this sort is usually plain So is that of the querulous resentful type of reaction *e g* in the man who believes himself done out of his rights and who becomes a persistent litigant or writer of memorials Before judging such a man psychopathic the extent of the injustice he has suffered must be compared with the degree of his resentment and his relevant conduct Commonly the injustice is found to be fanciful or trifling and the man s sense of grievance immoderate so that he comes to believe there is a veritable conspiracy to wrong him and devotes most of his time to useless appeals or threats He may persuade his wife or his children of the justice of his complaints inducing delusions in them *i e folie à deux* etc Many such patients however never become deluded they are contentious about their wrongs and waste years perhaps in proclaiming them or seeking redress but they are well aware how other people regard them and what has actually happened Many claimants of compensation grousers old soldiers and unstable adherents of more or less cranky movements are to be placed here There is no sharp dividing line between these psychopathic people and the more or less normal often socially precious leaven who detest injustice and are willing to do much to defeat it

HYSTERIA

In hysteria symptoms of illness are represented by the patient for the sake of some advantage without his being fully conscious of this motive The form of representation will vary widely according to the circumstances that have provoked the illness the patient s experience of what the symptoms are that he is trying to represent and his somatic resources These factors presently to be discussed bear on the hysterical symptoms that simulate physical disease But it is impossible to restrict hysteria to this physical form The illness that is represented by the hysteric may be a mental one moreover it is not possible to consider hysteria without regard to the mechanisms of its occurrence which manifest themselves in the personality and are mainly psychological Hysteria is the most psychogenic of all illnesses Its recognition is therefore a double problem (1) exclusion of what may be called genuine illness *i e* of a recognised morbid pattern and (2) discovery of an adequate motivation To ignore either of these requirements is to court error since hysteria may occur along with physical or mental disorder elaborating upon it and mimicking it and on the other hand some physical diseases give rise to symptoms indistinguishable in their form and apparent psychological mechanism from those of hysteria

Ætiology—A hereditary factor is probable in many cases Thus a group of hysterics who were pathological liars were compared with the average population in respect of the proportion of their brothers and sisters who were in mental hospitals it was five times as many and of the parents of the group a sixth were psychopathic From these and similar figures it is not possible to tell the mode of transmission or

that in the present state of psychiatry the value of a new therapeutic procedure should be assessed not by the reports of enthusiastic pioneers, invaluable though their efforts and observations are, but by the outcome of a planned therapeutic trial in which uniform standards have been employed in the selection of cases the method of administering the treatment and the assessment of outcome also due regard must be paid to the choice of those control " cases with which the beneficiaries of the new method are to be compared

The insulin method consists in the induction of hypoglycæmic coma daily for not longer than 3 months It is seldom desirable to exceed sixty comas The coma is allowed to last a variable period according to the clinical condition If unduly prolonged, it may be difficult to terminate it by the usual method—the administration of carbohydrate through a nasal tube or intravenously Persistent or irreversible coma is the chief danger of the treatment about a sixth of those who pass into such a state die Because of this and other complications mostly avoidable the insulin method should only be used by experienced persons in a hospital adequately organised and staffed for the purpose The treatment is most effective in cases which would have a good prognosis for the attack if treated by other methods In a series of more than a thousand patients treated with insulin, 13 per cent recovered and were still well 2 years later, at which time there were also 14 per cent much improved Such figures are so much influenced by the choice of patients that they cannot easily be compared with the results of other methods In the main however they speak in favour of the insulin method if applied with discrimination skill and willingness to use other methods also, during the administration of insulin or afterwards Frontal leucotomy has been employed in otherwise intractable cases, and some patients thus treated have become easier to look after or fit to leave the mental hospital

The details of treatment whether in hospital or at home must be individual even in such matters as the allaying of excitement no uniform procedure, *e g* continuous baths or narcosis can be a routine measure When excitement is extreme disturbances in water metabolism and loss of salts may be combated by giving 5 per cent saline intravenously 300 ml every other day alternating with forced fluids During stupor general measures for ensuring adequate food (in some cases feeding by tube) cleanliness and evacuation of urine and fæces must always receive attention It has been found that various chemical agents such as carbon dioxide inhaled in a 30 per cent mixture with oxygen and sodium amytal will temporarily interrupt a catatonic stupor this finding accords with the metabolic changes reported in the condition but its therapeutic value is slight

PARANOIA AND ALLIED STATES

The words paranoia and paranoid are used loosely by many Kraepelin gave paranoia its modern meaning describing it as the endogenous insidious development of a permanent and unshakable delusional system with complete preservation of clarity and order in thought will and action If the illness cleared up if it showed symptoms of an organic affective or schizophrenic syndrome or if it was provoked by external happenings it could not be paranoia Thus delimited the condition is exceptionally rare so rare indeed that there is no use in having such a category Moreover cases that Kraepelin himself called paranoia have since become obviously schizophrenic The same is true of paraphrenia There is now no profit in thinking of paranoid states as syndromes in their own right so to speak and of the same order as schizophrenia or affective disorders They are on the same subsidiary level as stupor hypochondriasis anxiety and depersonalisation When met with they must be distributed according to the accompanying symptoms and the

emotionally charged out of which the patient s symptoms will bring him more or less overt but unacknowledged gain This gain need not be material and obvious and may run directly counter to such accepted values as health and ability to work One of the plainest instances of a partial unsubstantial gain is that created by an injury and the resulting insecurity and claim for compensation or pension hysterical symptoms flourish in such a soil and are usually influenced for the worse by repeated medical examinations Hysteria occurs among soldiers under active service conditions and can readily be fostered in them by injudicious measures

Pathology —This is almost wholly a matter of psychopathology It is true that disseminated sclerosis and many other organic diseases of the brain may be accompanied by hysterical symptoms but the association is not a constant one The psychological changes can usually be traced further back than the happening that provoked the illness often they are the continuation of normal tendencies of childhood that have been fostered and extended by ill judged upbringing The hysterical symptoms that appear as motor or sensory phenomena show the patient s readiness for the translation of experience into bodily symbols this is a special instance of the universal tendency for somatic representation of experience converting it into action It is the facility and exaggeration not the existence of this conversion mechanism that is characteristic of hysteria What is thus translated or converted into physical terms has been something painful and unacceptable the partial exclusion of it from consciousness repression' of it is therefore understandable in its physical symbolic form it is tolerable and may even be prized Identification with other people is responsible for the frequent imitation of symptoms and for the epidemics of hysteria Clearly the mechanism need not be limited to the production of physical symptoms though bodily structure and local weaknesses may conduce to this There can be hysterical phenomena such as the dissociation seen in fugues and so called splitting of personality which are instances of the exclusion of recent and remote painful experience from clear consciousness The wishes and fears that deviously attain outward expression as hysterical symptoms do not derive solely from the recent past though much of their strength may come from it It must be admitted that there are some hysterics in whom this psychopathology cannot be demonstrated and that such cases are among the most intractable

Symptoms —These may be divided into (1) sensory (2) motor, including fits and (3) quasi psychotic

The symptoms can be like those of any conceivable affection of which the patient has a notion The cruder his notion the less will his symptoms be like those of the simulated condition but after he has been demonstrated to a class or repeatedly examined he may better his notion and consequently his symptoms come closer to those of organic disease Or if he has had opportunity of seeing insanity his pseudo insanity may smack less of the stage than it otherwise usually does The range of hysterical symptoms is so great that to describe them all in detail would take inordinate space and there is no need to do so

The *sensory* or more properly the *perceptual* symptoms include clavus and globus hystericus blindness deafness and anæsthesia The two former are so common in all sorts of mental disorder especially those accompanied by anxiety that they are of little specific importance in hysteria enquiry as to their presence will often in these rather hypochondriacal patients lead to their occurrence The difficulty in swallowing reported by hysterical women may be associated with a strong disinclination to eat—anorexia nervosa it should not be confused with depressive anorexia or that of pituitary cachexia Any cutaneous disturbance of sensation that the patient has a notion of can be presented *e g* anæsthesia either mono or bi lateral, or of stocking and glove distribution and analgesia of any part The anæsthesia seldom corresponds to any nerve trunk nerve root or spinal segment unless the patient has had special opportunities of knowing With an anæsthetic hand objects may be

the nature of what is transmitted but only to infer a hereditary factor The occurrence of hysterical mechanisms in children, and their frequency in *healthy adults* especially after calamities or in unendurable conditions such as may occur in war suggest, however, that hysteria is potentially present in most people and that environment is more important here than heredity The combination of heredity and environment may result long before actual illness occurs in a *hysterical personality* This is not found in all patients who show hysterical symptoms but nearly all people of hysterical personality show hysterical symptoms Many of the features of this personality are socially obnoxious but other features are not and it is wrong to use "hysterical" as a depreciatory epithet for a set of qualities that one dislikes These people are unduly responsive to the situation they are in especially if by their excessive response they can fulfil wishes of which they are hardly aware or evade what is painful in the situation, instead of meeting it and disposing of it adequately Unsatisfied with their own capacities, they seek to cut a better figure than their endowment warrants and are constantly posing and pretending This like all their behaviour and aims here described is not done with full consciousness but with a more or less sincere ignorance or ambiguity of purpose it is not a question of deliberate deceit of studied histrionics or malingering In thus responding to situations and turning the response to some inadequate end the hysterical person is characterised by a lack of inner stability and of constant standards of behaviour, and also by a lability of affect and an exuberant fancy The fantasies normal in childhood are here seen in physically mature adults who like children can temporarily live their fantasies absorbed in this unreal compound of past experiences and longings yet not so wholly divorced from their real surroundings as might appear In an attenuated form this is evident when they almost unwittingly manufacture some situation according to their needs—literally ' making a scene —and enter into it emotionally with a rapidity and fervour impossible for more stable people Egotism and untruthfulness (pseudologia phantastica) may be pushed to the point of delinquency There may be a longing for prestige sympathy love or some other emotional relationship, which leads the hysteric to behave in a way strikingly out of keeping with his demeanour on other occasions the inappropriateness of his behaviour even at the time may be obvious to a detached onlooker, but is not always so Many of these people can use illness or well acted fantasies of illness to satisfy their hardly conscious needs they may also gain their ends by forgetting what it would be painful to remember Here again the onlooker may find it hard to tell how genuine or complete is this forgetfulness but the question is of little moment compared with discovery of the motive for the hypomnesia Hysterics are often regarded as unduly suggestible because they respond so readily or violently to situations and to people with whom they develop an emotional relationship often unrecognised by themselves as such The emotional attitude of a hysteric towards others is often influenced by sexual factors Hysterical personality is believed to be commoner in women than in men and may be associated with psychosexual immaturity Coquetry and frigidity are not uncommonly allied in hysterics there may be much flirting and sexual excitation stopping short of coitus It is however juster to say that the sexual lives of hysterics show instability and inadequacy than to specify any particular aberration

Hysterical personality can be recognised before puberty in younger children however it must be extreme to be recognised because of the great frequency of such mechanisms normally then (*e g* behaving as though fantasies were real counterfeiting illness somnambulism) Some of the grossest instances of hysterical behaviour have been recorded in girls not yet adolescent *cf* the Salem witches Much of the work of child guidance clinics is taken up with the treatment of hysterical tendencies not perhaps taking the form of definite symptoms but plainly evident in the child s personality

The precipitating factor for the onset of hysterical symptoms is usually a situation

They may be little more than a fainting attack or an outburst of temper, significantly like the tantrums of an ill behaved child Often however they are more differentiated than this and diagnosis from an epileptic fit may be difficult Sometimes the fit grows out of a tremor induced by fright or anxiety or it may express some emotional state such as great pain anger or erotic excitement Occasionally the patient shows plainly by her expression and movements that the fit is erotic it may be a typical orgasm The ' classical four phase fits which Charcot described were artefacts of the clinic, they do not happen now

Sometimes the patient s fit becomes very like an epileptic one after he has spent some time at a neurological clinic, or he may be an epileptic who also has hysterical fits Some hysterics by overbreathing induce an epileptiform convulsion which can be abruptly terminated if an injection of calcium chloride or gluconate be given They may pass from one such fit into another so that the condition suggests a status epilepticus The unconsciousness that often appears to accompany a hysterical fit is seldom as complete as it looks neither is the subsequent amnesia There may however be a delirium corresponding to the emotional upheaval Patients very rarely hurt themselves seriously in the fit however violent or have a fit when alone or asleep The length of the attack and its degree often depend on the audience, the more the bystanders try to restrain the movements the wilder do the kicking, struggling biting shouting panting spitting etc become and the longer they go on There is neither the pallor nor the cyanosis the regular sequence nor the subsequent headache and sleepiness of epilepsy, urine is not passed nor the bowels opened reflexes including the corneal response are unaffected and the end of the fit may be abrupt

The *quasi psychotic* symptoms are stupor, twilight state pseudo dementia and fugue In the stupor seen typically in harassed weary soldiers under bombardment the patient lies motionless taking food like a 12 months baby non resistive sometimes incontinent of urine or fæces and without any predominant emotional tone It is of brief duration if the exciting circumstances cease to prevail In less acute forms there may be a sullen resistive akinesia or a condition lasting even for years with an occasional break this is a rare form Only with great caution and reserve should such stuporose or semi stuporose conditions be regarded as hysterical physical factors often play a large part in causing them or they may be schizophrenic The confusional or delirious states may accompany a fit or represent an important emotional experience *e g* some sexual episode They are often histrionic and represent wishes of a religious or grandiose sort or the patient may behave as though he were an animal or a child Sometimes they occur during the night and in a somnambulist state the patient repeats some past happening or may do complicated work This is closely akin to the hysterical fugue in which there is not so much a clouding as a narrowing of consciousness a dissociation In the fugue the patient says he has forgotten some or all of his life before a certain date and later he may profess to remember nothing of what has happened during the fugue There is in short a double set of memories which may alternate and since the patient s own identity is commonly included in the repressed and temporarily forgotten material he may be said to have two personalities and sometimes three or four Actually there are no cases in which it is strictly correct to speak thus of multiple personalities it is only a matter of different aspects or fragments of the one personality In the fugue the patient may live out some fantasy or—as more commonly happens—simply says that he does not know who he is or where he lives Nearly always a hysterical fugue with gross amnesia turns out to have been a means of evading some predicament and it is well to keep in mind in such cases that the patient may have broken the law or otherwise exposed himself to disgrace and punishment The amnesia is seldom as complete as the patient states Fugues may occur as a hysterical mechanism in an organic psychosis for example in a man with arrested general paralysis who had been prominently and in detail reported as a case of multiple personality which

identified and any test which the patient does not recognise as referring to this disability he will perform satisfactorily Such tests are not a means of catching the patient out as though he were a malingerer, but of *ascertaining whether the symptoms express only his notion of some illness* The tests for a malingerer, it is true amount to the same thing though one assumes the malingerer to be clearly conscious of his purpose consequently any distinction between *hysteria and malingering must* depend on the observer's impression as to the patient s honesty and self knowledge certainly it cannot be decided by tests The tests for blindness (*e g* using a stereoscope with a supposedly blind eye) deafness (*e g* effect on pulse respiration and psychogalvanic reflex of exciting remarks addressed to the patient) and for other forms of perceptual defect all depend on the physician s greater knowledge of what should or should not accompany the symptoms of which the patient complains they are not intended to discover hysterical " stigmata or characteristic anomalies The ovarian and other hyperæsthetic spots the pharyngeal anæsthesia and the concentric limitation of the field of vision formerly used diagnostically were all products *of suggestion or, as in the last instance* phenomena that may occur in normal fatigue in hypochondria and in certain cerebral lesions

The *motor* symptoms are paralyses pareses spasms contractures and tremors Hysterical paralysis or paresis never affects individual muscles but always movements By various devices it can be shown that the patient can still use the affected muscles as long as he does not know that the movement in question requires their use The paralyses affect chiefly the left side of the body are common in the *legs* (preventing proper walking or standing) and often occur in limbs or other structures that have earlier been the seat of an organic disability *e g* trauma or paresis If the *paralysis be flaccid no loss of tone or of reflex response is found, and the patient,* through his ill informed notions of what should happen behaves otherwise than a patient with organic paralysis would—*e g* if asked to rise from the supine to the sitting *posture without using his hands he keeps his paralysed leg flat on the* bed If the paretic part be kept stiff the antagonists will be found to come into action first when the patient is asked to perform the movement he says he cannot and if the movement has to be made against resistance sudden removal of the resistance reveals how much of the apparently tremendous effort was going into associated irrelevant or antagonistic movements Passive movement to overcome the spasticity or subsequent contractures cause the patient to be more upset than could be accounted for by any pain he may complain of The varieties of abnormal gait are numerous many of them fantastically elaborate and from the look of them exhausting Not only the musculature of the limbs may be affected but of the trunk (leading to curvatures and odd postures) and indeed any voluntary muscles *e g* of the tongue larynx pharynx or eye In hysterical aphonia the voice may sink to a whisper or there may more rarely be complete mutism the voice can however be used normally for coughing and similar purposes *The aphonia often comes on after some local inflammation* that has caused hoarseness or after a fright. Stammering usually of the exaggerated kind may also occur Spasm of the external ocular muscles leading to a convergent squint *may accompany a spasm of accommodation* Ptosis and blepharospasm sometimes occur Many of the tics and spasms that used to be thought hysterical are now recognised to be often physiogenic, *e g* residual symptoms of encephalitis *lethargica and chorea* spasmodic torticollis for instance is far less often psychogenic than used to be supposed When a spasm or paresis has long been maintained trophic disturbance may follow blueness and œdema shiny skin fibrosis of periarticular structures and similar effects of rigidity and disuse Tremor may occur and is often gross as in many of the war cases It is variable in degree and *rhythm and often* disappears when the patient s attention is turned from it this however is not a safe criterion

Hysterical *fits* commonly occur in patients with obviously hysterical personality

of some physical disease It is however in neurology that the most difficult cases of all arise e g in disseminated sclerosis carbon monoxide poisoning cerebral vascular disease or encephalitis lethargica here there is more likelihood of the organic disease being overlooked than of its being wrongly diagnosed The patient s previous personality any provocative situation or emotional disturbance the previous occurrence of organic signs e g transient diplopia and the age of the patient must be considered Hysterical symptoms appearing for the first time in middle or later life in someone whose personality has been stable are probably not solely psychogenic If the symptoms diminish when little or no attention is paid to them they are more likely to be hysterical

Course and Prognosis —This depends mainly on the patient s personality and social setting and on the treatment employed A long history of hysterical traits prior to the illness a continuance of circumstances favourable to the symptoms and inadequate or excessive treatment are all unfavourable This is however an illness that sometimes confounds prediction patients recovering when many adverse factors have been operative and the symptoms have been present for years In children the prognosis is fairly good if treatment can be undertaken promptly it is best if the hysteria is monosymptomatic and has come on after a fright In all cases in which the situation which provoked the illness persists the outlook is bad for example in compensation cases for which no medical treatment is of any avail—for obvious reasons—until the litigation is settled once and for all Similarly during war psychotherapeutic successes are often dazzling while the hysterical soldier is under treatment in hospital but the symptoms come again when he must return to duty There are many varieties of outcome chronic invalidism being the commonest A few patients later become schizophrenic and a few become involutional melancholics The prognosis in respect of the patient s hysterical personality is more important than that of his hysterical illness it is however no more to be assessed by rules than the general future of any human being s life and personality Patients do not necessarily tend to become anti social delinquency is certainly a likelihood in some hysterical people but bravery and self devotion may be conspicuous in others

Treatment —Too much treatment is worse than too little Injudicious physical or psychological treatment of hysterics often makes their symptoms worse and their illness intractable Recondite methods should be eschewed by all but experts Common sense is as important as psychological understanding and social usefulness more to be aimed at than removal of symptoms or attainment of self knowledge In short it is not the hysterical illness or the mechanism of repression and conversion that calls for remedy but the patient s inadequate way of dealing with difficult situations Consequently the whole treatment must aim at the patient s return to ordinary conditions of life as soon as possible and at a re education of his ways of meeting difficulties To this end it is profitable to go over with the patient the situations emotional disturbances and motives that led up to the illness and to do this without implying moral judgement or social indifference—certainly without teaching the patient one s psychological theories It is a matter of general psychotherapy (see p 1619) and it may entail a far reaching analysis of the patient s past life her emotional development and her instinctual tendencies It is questionable however whether anyone without special psychiatric experience is wise to enter lightly upon this way of benefiting the patient For on the one hand he may be misled into a wilderness of fantasy masquerading as once repressed now recalled psychic trauma and on the other he may be at a loss how to deal with the attachment and dependence upon him which the patient will come to show and which may in fact be the chief influence in bringing about her precarious recovery A great deal may be achieved—perhaps as much as by more thoroughgoing methods—if the physician himself mature and with impartial insight into the psychological motivation of the symptoms leaves aside in his dealings with the patient any very detailed enquiry into the more remote

responded to psychotherapy Psychogenic fugues are not invariably hysterical, they may be symptoms of a reactive depression in which despair and perplexity are conspicuous

'Pseudo dementia" covers the large group who behave as though insane It may occur, as in the so called Ganser syndrome, *in prisoners awaiting trial* Whatever the circumstances, its motive is escape from a disagreeable situation It is likely however that it is mainly those with a predisposition towards severe mental illness especially schizophrenia and the high grade defectives who have recourse to this *kind of hysterical behaviour* It sometimes comes on after brain injury The patients behaviour corresponds necessarily to their notion of insanity which is usually far enough removed from anything the psychiatrist knows as such Occasionally, however, it is very near the buffoon like conduct of some schizophrenics The patients say that they do not know their own age affect not to understand simple remarks give absurd answers which nevertheless indicate that they know the right answer (*e g* by inverting the correct order of the figures in a sum) When asked about some simple matter they look as though they were making terrific efforts to remember (herein behaving differently from the schizophrenic) The most characteristic thing is the disparity between the patient s alleged deficiencies and his general alertness he says he does not know anything about his own past, he cannot read or spell or do the simplest arithmetic and yet he may be behaving quite naturally and adapting himself to the situation in a way which would be inconceivable if he had actually so advanced a dementia

Some hysterics go to great lengths in their representation of ideas of illness They will allow *themselves to be put among grossly insane people or submit to repeated* operations, such as amputation Self inflicted injuries *e g* keeping wounds and sores open are not uncommon (cf dermatitis artefacta) In some such cases masochistic tendencies can be recognised but by no means in all Suicidal attempts are not *infrequent They often have as their purpose revenge the satisfaction of some spite*, and the patient may leave behind a lying fantasy coloured letter, indicting someone Frequently the suicidal attempt is in the nature of a theatrical demonstration, carried out in such circumstances as make it unlikely to be fatal, and if the patient kills herself, it is more through bad management than intention

Diagnosis—It will be plain from what has been said that diagnosis must be both negative and positive—negative, by excluding any organic cause for the symptoms positive, by finding motives and relating the symptoms to them Neither method is alone sufficient because of the occasional concurrence of structural disease with psychogenic symptoms As to the former *i e* the negative method it is unnecessary to enter here into all the differentiating points Many of them have been mentioned in the foregoing description of symptoms and all turn on the disparity between what experience tells us would occur if these symptoms were of organic origin and what the patient knows about such matters Consequently a doctor who has hysterical symptoms is extraordinarily difficult to diagnose in this negative sense The method of arriving at a diagnosis by suddenly taking the patient unawares and seeing if his symptoms persist is to be deprecated it antagonises him Likewise undesirable is the procedure of seeing whether one can suggest new symptoms to the patient *e g* an anæsthesia, it can be both misleading and harmful Neither is the hysterical nature of a symptom to be judged solely by whether it can be removed by suggestion for some organic symptoms are temporarily got rid of thereby and many *hysterical* symptoms are not An intimate knowledge of the range of symptoms of physical disease is much more useful to the physician than an equipment with special tests and lists of differences between functional and organic It is not only a problem of neurology but of the whole of medicine since the hypochondriacal tendencies of many hysterics lead them to complain of visceral symptoms usually in doubtful cases, the symptoms are those which might well occur in the earlier stages

Marriage should never be recommended as treatment for hysteria the superstition about this has resulted in lamentable troubles especially for the person the hysteric marries This is not to say that every hysteric is to be dissuaded from marrying there are more things than treatment to be considered then Married hysterics, however should not be recommended to have—or to adopt—a child Contrary to popular notions pregnancy and puerperium more often aggravate than benefit hysteria Moreover hysterical women are not usually satisfactory parents and commonly induce psychopathy in their children

ANXIETY STATE

As already stated the emotional syndrome so called is part of the group of affective disorders in which depression and manic excitement are also included It is there described It would be indefensible to put into a special category all the forms of mental illness in which anxiety is conspicuous for it can be severe in the most diverse conditions ranging from delirium tremens to schizophrenia The outwardly mild form tending to chronicity and often largely psychogenic responds well in the less advanced stages to psychotherapy it is therefore important that its recognition should not be delayed because of a doubt as to physical disease Yet often the correct diagnosis is overlooked while the patient is being investigated or treated for some local disorder This arises partly because of the quasi physical signs of fear which he may show—dizziness tremor nausea and vomiting indigestion diarrhœa palpitation a sense of oppression in the chest rapid pulse flushing sweating frequent passage of urine etc It is still more due to the patient s anxiety turning on his health especially his physical health and leading him to ask for more and more medical opinions radiograms laboratory investigations etc the favourable results of which however do not allay his worry Over cautious advice as to régime based on a possibility that there may be some early physical disease can be harmful to the patient s mental health in that it restricts his normal life and may constantly recall and reinforce his anxiety The converse error of mistaking some early symptoms of physical illness for hypochondriacal anxiety is equally to be avoided Physical investigation of doubtful cases is in short indispensable and should be prompt as well as thorough When it fails to confirm the presence of a physical disorder the patient should not be treated as though he will still be in danger of the physical illness unless he takes special precautions in diet exercise etc This is well illustrated by such a condition as effort syndrome where care taken to avoid any damage to the heart intensifies the illness The patient should be fully investigated on the psychological side and treated accordingly this does not mean that he should be treated only by psychotherapy The discovery of a possible psychological cause for the symptoms does not prove that there is not also a physical cause for them but it makes it less likely The converse is also true For ætiology diagnosis prognosis and treatment see section on Affective Disorder (pp 1645 to 1651)

OBSESSIONAL DISORDER

Definition —In this condition the characteristic feature is that along with some mental happening there is an experience of subjective compulsion and of resistance to it Commonly the mental happening (which may be a fear an impulse or a preoccupation) is recognised on quiet reflexion as senseless nevertheless it persists

Ætiology —INTRINSIC —The hereditary factor is strong A third of the parents *of obsessional patients and a fifth of their brothers and sisters have themselves* shown pronounced obsessional traits the proportion is in each case higher if all forms of mental abnormality be included since both schizophrenia and affective illnesses occur

causes of the illness and the purposes it served, and instead directs her towards a better social adaptation by advising her to avoid when possible the situations that, as he sees favour the production of symptoms getting her into a disciplined way of living and stepping in with explanation support and advice whenever fresh difficulties arise His success in getting rid of individual symptoms at the beginning may be an important factor in establishing the necessary relationship with the patient Such a line of treatment is not heroic or dramatic and it demands a great deal of the physician but it avoids some of the commonest blunders and may be strikingly successful For this or indeed any treatment admission to hospital is not essential but it will help when there are adverse factors in the patient s situation and of course will be essential if there be such symptoms as self injury, suicidal attempts pseudo dementia or gross paralysis The danger of the patient s picking up new symptoms in hospital should also be weighed Isolation is usually inadvisable

Many of the symptoms of hysteria will not wait upon general treatment but demand energetic intervention Anorexia for instance, cannot be allowed to go on to an avoidable inanition nor a paralysis to the stage of contracture a mute patient or one who is deaf or blind or ignorant of his own identity, offers such practical obstacles to almost any kind of treatment that the symptoms must be tackled and disposed of early For this purpose suggestive measures are valuable and appropriate physical treatment may be called for *e g* supervision during feeding or even tube feeding in anorexia nervosa physiotherapy for paralysis, voice exercises Suggestive measures need not take the form of hypnosis suggestion in the normal waking state has many advantages over hypnosis though those expert in the latter are sometimes very successful in their treatment Suggestion like almost every form of treatment of hysteria has pitfalls and its triumphs like those of every other method sometimes prove vain but in the hands of a physician who is at once confident and cautious this method may result in a satisfactory recovery If in using suggestion such physical devices as faradisation can be avoided it is better to do so As a means of demonstrating that the illness is not due to local disease however such methods sometimes take their place in a detailed plan of treatment Motor and sensory symptoms can usually be got rid of if the physician is patient determined and confident in the use of persuasion and suggestion Intravenous injection of a barbiturate such as sodium amytal may facilitate such treatment and may help the patient to disclose motives and happenings he had been reluctant or unable to talk about disclosures of this kind however must be received and utilised with caution and lasting benefit is not to be expected from such catharsis alone

The choice of occupation the settlement of any social cause of illness (*e g* claims for compensation) and the obtaining of a healthy attitude—neither complaisant much enduring nor harsh—on the part of the patient s relatives and friends are all important factors in treatment The hysterical reactions to injury call for special mention because of their frequency Though often of transparent motivation they are not by any means to be regarded as outright malingering for the patient s feeling of illness may be sincere his symptoms distressing his anxiety typical and his irritability and insomnia symptoms that he would gladly get rid off But they are none the less psychogenic It is often assumed that so far as an illness is psychogenic it must be treated only by psychotherapy This is false theory There are few mental disorders in which psychotherapy alone produces such small benefit as in the hysterical conditions due to the compensation or pension situation that may follow an injury Putting an end to the situation early and the resumption of ordinary activity as soon as any physical injury has been repaired are the most potent measures in the earlier stages Even if the symptoms have been present a long time the ending of disputes about claims and the return to ordered routine and regular occupation achieve more than do frequent medical interviews Psychotherapy is then an adjunct not an essential feature of the treatment

some forgotten alarm and take a queer form such as a phobia of lavatories or of one legged men It is loose usage to give the name phobia to every case in which an individual develops fear that is excessive or inexplicable, the essential features of an obsession already mentioned should also be present The term claustrophobia for example is often loosely applied to a fear or dislike of being in an enclosed place which is not obsessional Fears of dirt or infection are very common phobias they are symbols of moral usually sexual taint, and they lead to much washing etc thus a patient who has blamed himself for masturbation may be constantly washing his hands or following a complicated ritual of touching nothing with his bare hands for fear of contamination Often the rituals and defensive precautions seem grotesque when compared with their ostensible purpose as in the case of a patient who is perpetually putting himself to the greatest trouble in order to ensure that he never steps on a worm inadvertently Ludicrous as his behaviour may seem it is often tragic in the distress and indeed ruin it may cause him Another phobia is that which has fear as its object *i e* the patient is afraid of any situation in which he may feel fear some such patients do not leave their homes for years because they fear they may have agoraphobia once they get outside Obsessional *rumination* usually takes the form of endless questioning or search The patient has to ask himself Why with pointless insistence about all manner of problems beyond his or anybody s grasp or he has to keep casting round in his mind after some forgotten name or word which he could easily do without Religious scruples sometimes fall into this category as when a penitent is continually running to his confessor with some venial trifle he has come upon in his interminable self questioning and doubt

Obsessional patients are in most cases depressed, their illness is a depressing one Besides this secondary depression, however there is frequently an association of a more intimate kind in which depression—or mania—is the essential or the main part of the illness and the concurrent obsessions seem to be symptoms of this affective disorder In such cases the obsessional illness is very often cyclical in its course Anxiety is a common accompaniment of obsessions in phobias it is most conspicuous The anxiety is inseparable from the patient s struggle against the subjective compulsion which is so alarming to his feeling of integrity in self and mind such a shock to his belief that he is a free agent Schizophrenic symptoms may be in the offing or actually present when the obsessional ideas are of the magical kind *e g* the patient feeling that the effect of his obscene thoughts upon others may be averted by some gesture or when his rituals are carried to bizarre lengths *e g* having to save the last drops of his urine because of some recurring doubt Depersonalisation may occur in the course of an obsessional illness

Diagnosis—If the essential features *i e* feeling of subjective compulsion and immediate resistance to this be kept in view it is seldom difficult to distinguish between obsessions on the one hand and delusions hallucinations ideas of reference or self reproach feelings of being influenced and schizophrenic stereotypies etc on the other The only difference between obsessions and many schizophrenic phenomena towards which the patient retains insight and which he regards as alien to him lies in the nature of the compulsion he experiences in obsessions it is subjective—he feels that it comes from within his own mind, whereas in the schizophrenic phenomena he feels that it comes from without it is imposed upon him It is a difference however that may be obliterated *i e* what was once obsessional may become schizophrenic but this is an uncommon outcome when the obsessional disorder is definite and well established In differential diagnosis it must be remembered that obsessions may occur in the course of almost any mental illness in a person of obsessional tendencies and that the psychological mechanism for the production of obsessions like that for hysterical symptoms is present in almost everybody in varying degree Consequently an illness is not to be regarded as obsessional unless obsessions are the chief symptoms

with more than average frequency in families of obsessionals The abnormal personality of the parents is probably also potent as an environmental cause Very many obsessional patients have for years before they became ill shown a rather characteristic mental constitution they are excessively cleanly orderly and conscientious sticklers for precision, they have inconclusive ways of thinking and acting, they are given to needless repetition Those who have shown such traits since childhood are often morose obstinate, irritable people others are vacillating uncertain of themselves and submissive Obsessional traits occur however in many people who never become mentally ill and in many who become mentally ill otherwise than with an obsessional disorder Consequently these traits cannot be rigidly held to be the forerunners or non morbid counterparts of obsessional illness

EXTRINSIC —The influence of strict morose cruel overconscientious or obsessional parents has just been mentioned It is difficult to weigh its importance certainly in some cases it plays no part There is nothing specific in the situations which supply the content of an obsession they might equally well have preceded hysterical symptoms for example in a person so predisposed Nevertheless, the fright or pain which once accompanied a particular experience or a long series of experiences must not be overlooked in working out the multiple causes of some obsession psychologically related to this experience

Encephalitis lethargica and a few other cerebral diseases may produce typical obsessional symptoms in persons previously free from demonstrable tendencies in this direction

Pathology —Apart from the difficult instances in which lesions of the brain are accompanied by obsessions, this is at present wholly a matter of psychopathology Some elements of an obsession are universal human attributes all little children tend to ritualise and repeat all human beings are at times uncertain of the rightness or sense of what they have done they try to avert trouble by symbolical acts and other magical devices whose effectiveness they may question (*e g* superstition), many normal people moreover have mild obsessions that do not bother them (*e g* scruples) The manifest struggle going on in the obsessional patient may be restated in terms of hypothetical instinctual tendencies Such attempted explanation cannot be verified, and it is more useful to pay heed to the repression, displacement and substitution which lead to symbolic representation of emotionally significant earlier experiences and to the protective mechanisms by which the patient tries to ward off the painful and overwhelming obsession with the result that he develops complicated rituals and similar devices which may be mistaken for the essential symptom The transition from obsessional to schizophrenic is easy to understand psychopathologically since in both some contents of consciousness are separated from the main stream

Symptoms —Obsessions are conveniently classified as (1) ideas or images, (2) impulses (3) phobias and (4) rumination These overlap constantly

Among obsessional *ideas and images* are tunes, phrases mental pictures of a disagreeable sort (*e g* of a mutilated corpse) and obscene associations (*e g* every cranny reminds the patient of a vulva) Obsessional *impulses* are often of a suicidal or aggressive character the patient may feel an urge to kick people in the street to push his friend over a cliff or to throw himself under a passing train In many other cases however, they are less alarming *e g* impulses to swear loudly in church or to laugh at a funeral or more of an intellectual sort such as an impulse to count and manipulate numbers senselessly or to avoid typing any word with a given number of letters or beginning with a particular consonant *Phobias* are closely bound up with the other varieties of obsession thus the patient who has an impulse to plunge a knife into his friend s or his own neck has an understandable phobia of knives the patient who is troubled by obscene thoughts whenever he looks at a naked statue develops *a phobia of museums* Not all phobias can be so accounted for, they may rest on

sometimes themselves In this it is like mental illness and calls similarly for psychiatric understanding and treatment But since they are not ill their behaviour must be attributed to abnormal personality, much as an aberration like alkaptonuria must be attributed to abnormal physical constitution All abnormality of personality that does not amount to manifest illness may properly be called psychopathic personality The term does not connote an evaluation of character according to how useful such a person is to society, nor is it a prediction about the likelihood of subsequent illness of a particular type, it is a descriptive term But people of abnormal personality will often come into conflict with organised society and with individuals more normally constituted they will be on the whole more vulnerable to stresses, their peculiarities intensified into symptoms of illness or proofs of delinquency will earn them pity contempt dislike punishment or compulsory treatment It is therefore common for ' psychopathic personality to be used as a pejorative term limited to those who will afflict society in some way—the anti social psychopath , the psychopathic tenth are significant phrases akin to psychopathic inferiority and the still earlier moral insanity or the term is used to denote those who stand in danger of insanity—the schizoid psychopath for instance It is however wrong to apply to the concept psychopathic personality so shifting and subjective a criterion as social disapproval nor can mental illness be assumed to be a certain outcome in even pronounced aberrations of personality Among mystics and poets men of action scholars and scientists are some who have properly been classified as of psychopathic personality , their abnormality consisting nevertheless in unusually high rare and valuable if peculiar qualities rather than in a blemish or handicap St Teresa Joan of Arc T E Lawrence Cavendish Cellini Tolstoy Mozart, Michelangelo—any hurried list of famous people that have been cited as examples of psychopathic personality testifies to this Apart therefore from any judgement about the good or harm they do to society people are said to have a psychopathic personality if they fall outside the wide range agreed upon as normal—not quite the same thing as healthy—yet are not ill Society being ordered as it is the majority of such abnormal people will at some time come into conflict with it or fail to meet its demands and their conduct will often rightly be called anti social The anti social group of persons with psychopathic personality is large its size will vary according to the culture in which they live and the allowances or opportunities it makes for them This is obviously true if their adjustment as adults to the demands of the community is the measure of their anti social trends it is true also of their development and the way in which social influences may be such as to foster their smooth participation in a very diverse pattern of human relationships or may mar them giving neither free play nor direction to their peculiarities Success in preventing many of these abnormal people from becoming a nuisance or a danger is therefore a test of the educational methods the pliancy and the psychiatric hygiene of a community This is not to ignore the hereditary and narrowly individual factors which determine psychic constitution but to stress the social causes of later social failure should it occur such failure however, need not be regarded as inevitable in people of psychopathic personality

Classification of psychopathic personality can be (1) arbitrary (2) psychological or (3) psychiatric The first picks out what seem serviceable characteristics that occur often and conspicuously thus one well sponsored list is made up of the excitable the unstable the impulsive the eccentric and perverse the quarrelsome the anti social and the liars and swindlers and makes further reference to æsthetes scatterbrains enthusiasts and fanatics The second which is the ideal method is based on the varieties of normal personality Unfortunately the types trait-clusters and other classificatory groups so far proposed do too little justice to the complexity and range of human personality to be satisfactory or lasting The third or psychiatric classification is likewise provisional but it has the advantage of grouping

Course and Prognosis —The outlook for recovery is worse if obsessional symptoms have been present since childhood if they now fill up most of the patient's time, and if he is weakly *resigned to his illness* *The best outlook* is when the obsessional illness comes on suddenly in a person who has not had conspicuous obsessional traits or who has had previous benign attacks A cyclical course is not uncommon The situation is ominous when the ritual gets more and more systematised and remote from what previously occasioned it The development along schizophrenic lines already mentioned, is more to be feared in such cases and in those with bizarre obsessional thoughts, the great majority of gross obsessionals however do not *become schizophrenic or anything else than obsessional* About *half* the cases recover from an attack which may, however, last for a year or even more Many people are subject to brief attacks lasting only a few days and largely due to fatigue or physical illness reducing their mental health Intercurrent happenings influence the course of the illness *e g* some men were free from symptoms during their period of war service with its routine and lack of responsibility or need for decision The content of the obsessions is of little use prognostically Old age is not in itself an adverse *factor but attacks in childhood suggest a strong constitutional bias and are therefore* unfavourable on the whole Few obsessionals give way to anti social impulses *e g* to suicide homicide delinquency It is true that obsessionals who are also depressed may kill themselves, and that obsessionals who are irritable and angry may injure others, but obsessionals rarely yield directly to an impulse they have resisted or need to have ' irresistible impulse urged in extenuation of a crime Sexual offences and perversions are rarely obsessional

Treatment —*Patients should be encouraged to continue at their occupation and* not to test themselves, or try to overcome their obsession, by repeatedly putting themselves in a situation in which it will occur So long as their impulses are not likely to get them into trouble they should be dissuaded from 'fighting' them external restrictions are more helpful than reliance on will power The physician should aim at getting a patient well by putting an end to his anxiety and struggle, if that is not wholly attainable the patient must be educated to deal with his obses*sional tendencies by acknowledging their existence their psychological origins* and often their harmlessness in those very respects in which he thought them most harmful, *e g* obscenity Frank recognition of obsessional tendencies which everyone has in some degree is an important step in learning to control them In some patients the obsessional attack is so cyclical and almost self limited that a brief rest and general care are all that are needed In others whose affection is chronic recovery is out of the question but advice about the management of their lives varying according to *their individual circumstances helps them greatly* In some such patients frontal leucotomy lessens or removes the distress that formerly accompanied their obsession Obsessional patients so prone to rumination and endless questioning often clamour to be psycho analysed There is no evidence that psycho analysis however prolonged benefits them more than methods that are not so exigent of *time and money* Obsessional children who may be beset with fears of contamination and religious scruples usually respond well to changes in their human environment advised after the physician has enquired into the family and school situation temporary separation from an obsessional parent or treatment of the latter often proves remarkably beneficial for the child Discussion of his problems with the child is an important adjunct of such treatment, just as it would be with an obsessional adult

PSYCHOPATHIC PERSONALITY

There are many who do not regard themselves as *ill nor do others think* them so yet their behaviour is abnormal enough to upset or puzzle other people and

and feeble mindedness begins Again as with mental disorder the same clinical picture may be due to a variety of causes ranging from heredity to trauma They are moreover delimited rather by social than by other criteria and they are not definitely associated with any constant pathological findings except in the numerically limited group of special clinical types In that they are capable of only limited improvement when well established and that the intellectual functions are more obviously damaged than any others their similarity to cerebral impairment in adult life is easily seen They are not by any means cases of purely intellectual defect they represent, it is true one extreme on the scale which has people of great intellectual ability at its other end but they are also examples of a general impairment of mind affecting the emotional and conative functions and often associated with a more general impairment of the whole organism, which may be seen in its physical structure Since the milder forms are indistinguishable (except on an arbitrary reckoning) from what may be termed normal stupidity it is difficult to use rigorously the official definition of mental defect as a condition of arrested or incomplete development of mind existing before the age of 18 years whether arising from inherent causes or induced by disease or injury but the description is serviceable It should be recognised that just as psychosis differs from neurosis only in a rough social sense turning on the need for special care and neurosis from normality only in respect of the limitations the former imposes on one s daily life as a social organism so does the distinction between normality and feeblemindedness and between gross or certifiable deficiency and the lesser forms turn on the social adaptation of the person in question To complete the points of similarity there is recognised a ' moral defectiveness which has its parallel in some kinds of ' psychopathic personality The effects of encephalitis lethargica parenchymatous syphilis and thyroid deficiency upon the mental state and development at different ages or the varying results of amaurotic familial idiocy in the infantile and the delayed juvenile form illustrate how important is the stage of growth or maturity at which damage is done

Ætiology—The customary division is into primary (hereditary) and secondary forms but a less dogmatic distinction is between those who represent the lower extreme of normal variation (the subcultural group) and those in whom a gross structural pathology is discoverable The former group is a large one making up approximately three quarters of all cases of mental defect This is an estimate arrived at by independent workers but it may have to be changed as we acquire better methods of determination and fuller knowledge of the subtle interplay between environment and heredity The grosser the deficiency the less important the hereditary factor except in some rare well defined anomalies such as amaurotic idiocy Familial concentration of a given form of defect is specific for each clinical type A combination of several genetic factors is probably responsible for all but the special types the mode of transmission of amaurotic familial idiocy and of phenylketonuria is recessive that of epiloia dominant

The environmental causes are prenatal congenital or infantile they include birth injury to the brain meningo encephalitis hydrocephalus cerebral syphilis Various poisons and deficiencies may be responsible, as in the well known instance of cretinism as well as certain malformations of the cerebral tissue *e g* microgyria and porencephaly, and of the cranium *e g* oxycephaly The influence of maternal rubella and other exanthemata and of Rh incompatibility upon the fœtus have lately been studied in this connection Sensory defects as in a deaf mute may greatly impair mental development It is possible that some cases of schizophrenia beginning in the first few years of life are indistinguishable from mental defect and are diagnosed as such

Pathology—In many cases there are no significant findings this is particularly the case with high grade defect It is probably impossible from the histological appearances to infer the extent of hereditary or exogenous causation Develop

these non morbid abnormalities in the same categories as the severe morbid ones (with which there is reason to believe them genetically connected) To do this begs some fundamental questions but it is for the present useful to recognise schizoid affective, paranoid obsessional hysteric and perhaps epileptic varieties of psycho pathic personality This list is open to the objections that must be made to any attempt at stating types of personality, and it is wrong to suppose that any of the varieties mentioned must always precede, or indicate proneness to the illness from which its epithet is derived Nevertheless they give the psychiatrist a familiar frame of reference and they leave room for manifold combinations of traits and attitudes within each class so that the individual drug addict the sexual pervert the hypo chondriac and the fanatic can be included If this psychiatric classification were to be judged by as rigorous a standard as the psychological it could not stand it will no doubt eventually give way before a surer psychology of personality and a surer psychopathology, as indeed it would have to now if the psycho analytical conception of the structure of normal and morbid personality were accepted as final For the time being it is convenient to use these derivative terms such as schizoid and to give them no more weight than the bare labelling of personality deserves Under standing a psychopathic person s motives and conduct of course requires full consideration of his development circumstances and traits and goes beyond their classification for clinical purposes

Besides the hereditary and social causes of psychopathic personality anomalies of cerebral structure may contribute to the condition But in childhood and even in maturity damage to the brain by infection, poisoning malnutrition or trauma can lead to changes in personality such as occur after encephalitis carbon monoxide intoxication, pellagra operations and accidental violence to the brain They do not conform to a single pattern and may be complicated by intellectual impairment They depend to some extent on the part of the brain affected, in perhaps the most striking group—encephalopaths whose emotional control is much reduced so that they easily become violent when they cannot get their own way—the hypothalamus and other structures in the rhinencephalon are suspect Electro encephalographic data have recently been added to the clinical psychological and experimental evidence for this Some writers believe that most of those with psychopathic personality characterised by violent outbursts have an innate or acquired cerebral abnormality and even though on inconclusive grounds that there is a kinship between the aggres sive psychopath and the epileptic It would however be a mistake to attribute psychopathic personality even when marked by excitability and impulsive acts of violence mainly to anomalies of cerebral constitution emotional deprivation or insecurity during childhood parental mismanagement and in adult life severe frustra tion and adversity constitute psychological causes which are often in evidence

Any description of forms of psychopathic personality must be lengthy as must also any consideration of their psychopathology and treatment Crime juvenile misbehaviour habitual or sporadic drug taking peculiarities of sexual desire and practice incapacity for certain occupations and public duties (*e g* school teaching military service) the temperamental concomitants of inferior intelligence and at the other extreme some of the characteristics of genius these are intimately linked with the problem of psychopathic personality, and their exposition would demand a fuller treatment than space allows

MENTAL DEFICIENCY

As already stated (p 1626) there is nothing in principle to separate these from other forms of mental anomaly save that they occur at an earlier stage of life Like mental disorder they shade into normality no man can say where stupidity ends

ways suggestible and accessible to flattery they may be obstinate and egotistical and readily fall into anti social courses e g prostitution vagrancy, crime Crude sexual offences or murder may be committed as lightly as some minor deception The personality of imbeciles varies widely some are docile and kindly others rough or deceitful and vindictive It depends much on their upbringing It has been found that in satisfactory conditions only about 8 per cent of defectives show anti social or troublesome behaviour But though the deviations of personality may not lead to delinquency, it is common to find in mentally deficient persons defects of tempera ment and character as well as of intelligence which are reflected in social inefficiency This is most important in the feeble minded who have intelligence enough to learn an occupation whether they can earn their living by it will depend on their character and the way they have been brought up

Many persons who are high grade defectives when measured by formal tests are not taken to be such because of their social adaptability, their fluency and capacity for keeping their heads above water as long as economic and other stresses are light There are instances of people classed as mentally defective during childhood because of their backwardness in school and their low score in tests who later in life amass money by their own efforts or even hold responsible positions A majority of high-grade defectives however live dependent and often troublesome lives at most they do simple repetitive work Many of them are unstable creatures whose psychopathic personality may be sufficiently anti social for the term moral deficiency to apply to them Hysterical trends may show themselves in crude phenomena e g con vulsions counterfeit insanity or fantastic lying and religious and artistic pretensions may take in gullible followers and even lead to the founding of ephemeral movements

Defectives are prone to disturbances of mood sometimes arising out of awareness of their inferiority and its social consequences Sudden outbursts of excitement may show similarity to manic or catatonic hyperkinetic states they may be accom panied by a paranoid hallucinosis mainly auditory which clears up with startling rapidity in a day or two In respect of these psychotic episodes defectives are like epileptics and juvenile encephalitics in whom a cerebral impairment has likewise occurred before the attainment of maturity Some of the morbid phenomena espec ially in idiots are very similar to the disorders of motility seen in schizophrenics because it may be assumed the same bodily mechanisms are implicated

The *mongoloid* type of defect is characterised by striking physical features Prob ably the outcome of intra uterine conditions it is most frequent in last born children in a large family or in children born of elderly mothers parental syphilis may occa sionally be the cause In many cases the brain stem and cerebellum have been dis proportionately small and other signs of maldevelopment have been reported Cere-bral metabolism is abnormally low It is likely that hereditary factors of an irregularly dominant nature also play a part The condition is usually present from birth physical growth is slow and has stopped by the time the child is 15 Defective growth of the skull leading especially to abnormalities of the base and the orbit are respon sible for the peculiarities of cranial shape The pituitary gland has been reported as showing an increase in eosinophil cells and deficiency of basophil cells The appearance of these usually happy idiots and imbeciles is rather suggestive of a Mongol or of a fœtus The skull is small and round and the junction of occiput and back of neck flat an epicanthic fold across each inner canthus narrow tilted eye slits and lids without lashes red cheeks fissured and often protruding tongue stubby depressed nose with nostrils looking forward irregular late appearing teeth coarse hair on the scalp small facial bones and occasional neurological anomalies such as nystagmus make the head of every mongoloid a disagreeable but ready index to his disorder That the disorder is a general one the rest of his body testifies his limbs are lax and over mobile at the joints he has broad clumsy feet and hands (with short fingers a special pattern between the base of the third and fourth fingers and a crease

mental anomalies such as general hypoplasia and microgyria may, however be mingled with evidences of a past lesion as in porencephaly or hemiatrophy or with signs of a disease actually present as in amaurotic idiocy cerebral lues and tuberose sclerosis Localised lipoid deposits in the brain are found in amaurotic idiocy Schuller Christian s disease gargoylism and Niemann Pick s disease

Symptoms —The usual classification is into idiots (who are too defective to be able to guard themselves against common physical dangers like falling into the fire) and imbeciles and feeble minded persons (who need to be looked after because of their incapacity to manage their affairs or to profit by instruction) Imbeciles cannot earn their living the feeble minded cannot get on in an ordinary school but may learn a good deal in a special school and be able to earn a living The criterion is in each case mainly a social one the same is true of moral defect', *i e* mental defect coupled with strong vicious or criminal propensities Although these terms are defined in an Act of Parliament they are vague and of administrative rather than medical use An attempt has been made to render them more precise by psycho metric means the customary tests for mental age (usually the Stanford Binet) are applied, and if the subject s intelligence quotient $\left(\frac{\text{mental age}}{\text{actual age}} \times \frac{100}{1}\right)$ be less than 20 he is called an idiot, if it be between 20 and 50 an imbecile if between 50 and 70 feeble minded It must however be recognised that though mental defect is mainly a matter of intellectual capacity it is not solely this and that intelligence tests how ever valuable and trustworthy cannot give a complete indication of the degree of mental defect Even the intellectual defect may be uneven showing much more in some tasks than in others, and it would be a gross error to suppose that a mentally defective person with a mental age of, say $9\frac{1}{2}$ years is mentally in the same state as a normal child aged 9^1 years

The *physical* symptoms are chiefly due to lesions of the central nervous system birth trauma may have led to paralysis spasticity athetosis or there may be evidence of an inflammatory condition of the brain and its membranes as from syphilis The whole clinical picture may be greatly coloured by the motor disturbance *e g* continual rocking and twisting movements grimaces and abnormal posture The special senses may be affected as the result of an independent anomaly *e g* coloboma misshapen ears or from a common cause *e g* interstitial keratitis the retinal changes of amaur otic idiocy It is dubious whether the stigmata of degeneration , such as a Gothic palate or a Darwinian tubercle occur any more frequently among defec tives than in the rest of the population at all events there is none that can be used diagnostically except in the case of mongoloid idiocy There are however some correlations between somatic anomalies and mental defect Thus there are more physical defects among these people than in the average population and this becomes more evident as one looks lower in the scale of mental defect in which skeletal and cardiovascular anomalies may fairly often be found sometimes but not always due to thyroid or pituitary disorders The mongoloid variety is described below

The *mental* symptoms are lack of intelligence and of the normal exercise and control of primitive tendencies This may be extreme as in idiots who cannot be taught to feed themselves and keep clean or who can only just recognise their com panions and make their elementary needs known—they are indeed much less intelli gent than an animal Imbeciles are usually incapable of learning and remembering any but very simple matters They may however be able to do automatically what they cannot understand or put to independent purpose thus idiots savants are especially clever at doing mental arithmetic recalling dates and other such operations What imbeciles manage to learn they cannot utilise in any but the most familiar circumstances Abstract concepts are too hard for them and their judgement is as poor as their grasp or awareness of what is relevant in any situation Though in many

has been standardised on a large adult population it consists of five verbal tests (of comprehension, information digit span forwards and backwards recognition of similarities arithmetical reasoning) and five performance tests (picture completion picture arrangement object assembly, block design digit symbol)

Tests of intelligence are by no means chiefly employed for detecting and measuring defect they have their main field of application in indicating a child s educability and potential attainment and an adult s capacity to undertake certain activities They are used for judging fitness rather than unfitness selecting rather than rejecting It must however be emphasised that intelligence measures cannot be regarded as a measure of height or weight might be they depend on the tests employed, they have varying reliability they cannot be translated into the language and recommendations of practical life unless the interpreter has a clear knowledge of the theoretical and technical limitations implicit in their method To take a self administering' test or a group test of intelligence and to draw merely from the score obtained on it by a child or adult the conclusion that he is mentally defective would be as inept and gross an error as to diagnose active syphilis merely because an unknown laboratory on one occasion reported a positive Wassermann reaction in the patient s blood

There are general observations about mental tests which it is particularly necessary for occasional or inexpert testers to bear in mind The scores must be accurately and as far as possible objectively arrived at therefore the personal opinion of the tester should not enter into them though his skill in administration may have influenced the result Any test which has not been standardised on an appropriate population cannot be safely employed since test scores have no absolute significance they must always be compared with norms and it is imperative that these norms shall have been collected on a suitable group since it would be misleading for example to judge an English child to be less intelligent than an American one because he could not do a test requiring familiarity with American habits and ideas A test to be satisfactory must be both reliable (measuring the subject s ability accurately and consistently) and valid (correlating effectively with other measures of the ability that is being tested) The validation of intelligence tests is a difficult matter sometimes it is carried out by comparing test scores with ratings of intelligence by teachers and other judges or with subsequent educational achievement, and sometimes by the statistical procedure of factorial analysis in which all the items in the test are compared with each other to see whether there is internal consistency

Intelligence tests are different from educational tests They are intended to measure native ability not acquired experience It is true that educational attainment depends largely on innate qualities but the more an intelligence test relies on tasks which demand some acquirement not equally available to all those tested the more misleading may be its results The application of this to verbal tests is obvious a subject who has poor command of English or who has aphasia cannot do himself justice on a test that is satisfactory for the bulk of literate people Performance tests which do not use words are not entirely free from similar defects and in spite of certain merits (greater attractiveness for children tendency to evoke informative temperamental reactions) have conspicuous disadvantages they are seldom cheap or handy, are often inconsistent and unreliable and have poor validity on some of them the subject s performance is much influenced by any emotional or neurotic disturbance he may have Consequently whereas a single predominantly verbal test like the Binet may suffice to indicate the child s or adult s intelligence (provided there is no special verbal difficulty) it would be unsafe to rely on one or even two or three performance tests a median or average score based on half a dozen performance tests is preferable

Group tests have become increasingly popular because they save so much time They are not suitable for testing young children (under the age of 7 or 8) are not so objective and standardised in application as they seem, are by no means foolproof

across the palm) protuberant belly *and low stature* and perhaps a congenital cardiac lesion The similarity in a few respects to juvenile myxœdema and the occasional concurrence of the two conditions sometimes make differential diagnosis difficult not all of the signs here mentioned need be present in any one case On the mental side there is a liveliness and amiability not often seen with so much intellectual defect the patients like music and little jokes of a primitive sort they will imitate gestures but seldom learn to speak properly with their rough harsh voices

The forms of deficiency due to *thyroid insufficiency* and *cerebro macular degeneration* are referred to elsewhere (pp 1483 and 1644) *Epiloia* is the name given to the rare condition in which tuberose sclerosis of the brain, adenoma sebaceum and tumours of the kidney and heart may be associated epilepsy is common and there are gross mental disturbances *Gargoylism* is a rare chondrodystrophy with hepato splenomegaly and mental deficiency In *phenylketonuria* there is increased urinary excretion of phenylpyruvic acid, phenyllactic acid and phenylalanine It is an hereditary disorder due to a single autosomal recessive gene the patients are typically fair haired blue eyed and blonde

Diagnosis —Recognition of gross mental deficiency calls for no skill The degree and kind of impairment however and the somatic variety or cause have to be worked out in every case The latter problem—a minor one except in the case of juvenile myxœdema and syphilis—is to be settled by careful physical examination and enquiry into the history The former is a matter of assessing intelligence and social aptitude

The assessment of intelligence is nowadays a matter of giving the patient tests which have been standardised on average samples of the population What is average or normal at a given age is therefore known and the defective child s performance can be compared with this The most popular and serviceable tests are modifications of those put forward by Binet and Simon in 1908 As these may give a rating that depends unduly on the child s educational opportunities and facility in language and may not indicate special abilities *e g* in mechanical matters many other tests have been worked out which supplement or in certain cases replace the Binet scale A child under the age of 5 cannot be satisfactorily dealt with by the Binet tests which moreover have only limited value for measuring the intelligence of adults It is difficult to agree about what in a normal child must be regarded as the limiting age at which he becomes of adult intelligence it is generally taken as 14 or 16 years In all tests the emotional state of the subject is a factor that may influence his performance The emotional reactions to being tested must be taken along with responses to more familiar situations *e g* at home or at school as evidence of the soundness or instability of the child s personality by such criteria must be judged the social development of the patient his fitness for living in the community or being put under lasting surveillance and control

Mental age and *intelligence quotient* are familiar devices for stating the results of the Binet test and its derivatives In spite of their convenience they are open to so many objections that they might well be dropped now in favour of a percentile scale or one in which test scores are converted into standard scores the statistical properties of which are known The percentile method which requires less familiarity with statistics indicates whereabouts on the curve of distribution a given score comes when a large representative sample of the population is tested Thus whatever the test the score obtained on it can with such a scale permit the conclusion that the person tested falls within say the upper 5 per cent of the population *in this respect* or within the bottom 1 per cent Valuable for children such a method of assessing intelligence (and other qualities) is particularly needed for adults in whom the mental age method is inapplicable Since it has become very plain that it is useful to test the intelligence of adults the inadequacy for this purpose of the Binet scale has led to its being superseded by several tests of which the Bellevue and the Progressive Matrices are probably the best known and most serviceable The Bellevue scale

APPENDIX

depending as they do to some degree on the subject's attitude and situation at the time, about which the group tester will know little or nothing and they cannot be trusted when a low score has been obtained In all instances where a decision must be taken that depends partly on the results of the test any puzzling or unduly low score on a group test should be reinforced by an individual test, such as the Binet or Bellevue It must however be admitted that the inexpert administration of individual tests can yield as rich a crop of wrong conclusions as can the uncritically accepted group test The truth is that ' no mental test score should ever be accepted at its face value nor trusted in the same way as physical measurements are trusted No one ought to use tests who is not willing to familiarise himself with the under lying principles which must be understood if tests are to be applied and interpreted properly and with the literature which bears on the particular tests that he employs In skilled hands testing provides a far surer and more accurate tool for the assessment of abilities than do subjective impressions or the ordinary examination paper But human nature is far too complex to be measured in the simple and direct ways in which physical quantities can be measured and the over enthusiastic but unskilled tester is only too likely to make serious mistakes '

Treatment —PROPHYLACTIC —Eugenic measures are desirable for the rare heredi tary conditions, like amaurotic idiocy, and in the case of those imbeciles and feeble minded in whom genetic rather than environmental causes have been responsible for their maldevelopment and who are capable and desirous of procreating, idiots do not procreate Voluntary sterilisation for eugenic reasons has been recommended by a Departmental Committee but has not yet been explicitly sanctioned by law Birth control, therefore, is the eugenic measure to be advised in cases in which defec tives seem likely to transmit their defect, unfortunately few such defectives can be relied on to observe contraceptive precautions effectively Segregation may indirectly serve the same end Well managed parturition and treatment of parental syphilis are the only other practicable ways of forestalling defect

Educational and social—Much improvement may be attained by the training of defectives it is work for experts Many high grade defectives who would otherwise spend their lives in an institution can be prepared by suitable graduated work under sheltered conditions for an independent life in the general community Where there are special disabilities e g of the senses, or of such capacities as reading and writing attention to these may lift the child out of the class of mental defectives altogether so may education designed to promote emotional stability and self confidence Whether a child lives at home or in a colony or institution will depend not only on the degree of his intellectual and social deficiency but also on the adequacy of his home circumstances There are many kinds of provision for the care of some of the 300 000 defectives in England and Wales ranging from special schools and statutory supervision to mental hospitals an eighth are in certified institutions and a thirtieth more in public assistance institutions Well run colonies providing adequate psycho logical and occupational as well as psychotherapeutic and other clinical services succeed in socialising many defectives hitherto vicious or violent who can then go out and live usefully in the community or in hostels Some, however prove intract able especially those who have epileptic fits

Physical—The bodily disturbances e g contractures and paresis call for ortho pædic treatment which sometimes benefits the mental state The treatment of the forms due to thyroid deficiency or syphilis is described elsewhere

AUBREY LEWIS

APPENDIX

HISTOPLASMOSIS

Definition —An acute subacute or chronic infection of man and certain animals by the fungus *Histoplasma capsulatum* giving rise to three main clinical types of disease (i) the disseminated form where the parasites invade the reticulo endothelial cells in many parts of the body (ii) the primary pulmonary form confined to the lungs and adjacent lymph nodes (iii) a localised infection of the skin or the mucous membranes of the mouth tongue or pharynx

Ætiology —The fungus exists in two forms (i) a mycelial phase which is found when it is existing as a saprophyte or if it is cultured at a temperature of 22 C (ii) a yeast like phase which occurs when it is living as a parasite or if it is grown on enriched media at 37 C Infection from natural sources is probably due to the mycelial phase but it is the yeast like phase that is parasitic and invades the tissue cells change from one form to the other readily occurs

The fungus has been isolated from the soil in many areas and some twenty species of animal have been found to harbour the parasite the bulk of natural infections being found in dogs cats and rats it has also been found in a high proportion of skunks and opossums but only small numbers of these animals have been examined Birds have not been found infected with *Histoplasma* and seem to be highly resistant to it though the fungus can be found in profusion in their droppings and in the litter of poultry houses A number of small epidemics have occurred on farms in the United States and amongst builders working in lofts where birds roost, caused probably by inhalation of infected dust The adoption of the deep litter method of poultry farming in this country suggests the possibility of similar outbreaks arising particularly in the more humid western counties Both sexes are susceptible at all ages the highest incidence being either during the first year of life or in the later adult years Amongst adults males are infected seven times as frequently as females

The chief portal of entry is thought to be the respiratory tract but the dissemin ated form may originate in some part of the gastro intestinal canal Primary skin lesions also occur but they are uncommon Special precautions seem necessary in laboratories as already 41 cases of infection with clinical illness have been reported amongst laboratory workers who had been handling *H capsulatum* The incubation period is not known with certainty but is thought usually to be from 4 to 6 weeks with a range of from 2 weeks to 3 months *H capsulatum* has a world wide distribution although clinical cases occur somewhat sporadically outside North America In Great Britain at least 15 cases have been diagnosed with certainty but it is thought that in the majority the infection was acquired elsewhere The principal endemic centre is in the United States of America where the greatest incidence is found in an area extending from the Great Lakes to the Gulf of Mexico in the valleys of Ohio Missouri Arkansas and Mississippi rivers

Pathology —The fungus invades and multiplies within the reticulo endothelial cells and in the disseminated form it may be found throughout the body or confined to a single organ the suprarenal glands often being the principal or only organ involved In acute disseminated infections with a fatal termination intra cellular organisms may usually be found post mortem in stained sections of tissue from the lung liver spleen and suprarenal glands The gastro intestinal tract is often affected and the bone marrow almost invariably The organism produces greyish white nodules usually multiple varying in diameter from 2 to 3 mm up to several centi metres Extensive areas of necrosis may be found surrounded by granulomatous

organism is found most easily in smears obtained by sternal or splenic puncture but may also be seen in smears from the lesions where these are accessible and at times in the cytoplasm of the mononuclear blood cells Very occasionally in heavy infections a direct sputum smear will show the organism

Culture—If the infection is scanty culture will be necessary and this is the method for definitive diagnosis Cultures should be made on enriched blood agar to which small quantities of penicillin and streptomycin have been added Infected material such as blood bone marrow or sputum should be rubbed over the culture medium the plates then being closely sealed with cellophane tape It is essential to incubate some of the plates at room temperature as at 37 C only yeast like bodies are produced At room temperature an abundant aerial mycelium is formed consisting of septate hyphæ with numerous microconidia attached to their sides or growing on short lateral branches In addition there are the rounded tuberculate chlamydospores which are characteristic of *H capsulatum* and their presence makes diagnosis conclusive The material used for culture must be fresh and the cultures should be observed for 6 to 8 weeks before they may be considered negative

Histoplasmin Skin Reaction—The histoplasmin skin reaction develops within a few weeks of infection 0 1 ml of a 1 1000 dilution of standardised histoplasmin is injected intracutaneously The reaction is read after 48 to 72 hours in the same way as for the tuberculin test A positive reaction is found not only during the clinical stage of the disease but in many healthy persons living in endemic areas As such reactors have an unusually high incidence of pulmonary calcification it seems probable that a past infection with *Histoplasma* has healed spontaneously without causing any recognisable illness

Complement Fixation Test—In acute infections complement fixing bodies appear in the blood towards the end of the third week of the illness and increase during its course gradually diminishing as recovery sets in In chronic pulmonary infections they may persist at a high level for many years The complement fixation test is a valuable aid to diagnosis and should be employed whenever infection by *H capsulatum* is suspected The test may become negative in the terminal phase of the disseminated form of the disease but the fungus can then usually be identified readily by blood or bone marrow culture or by the examination of tissues obtained after biopsy has been performed The antibodies produced cross with the antigens of other fungi particularly *coccidioides immitis* and *blastomyces dermatitidis* These cross reactions do not however invalidate the complement fixation test as the titres of the homologous antigen are significantly higher

When biopsy is possible sections of enlarged lymph nodes or of tissues from superficial lesions may show endothelial cells packed with *H capsulatum* Caution is necessary however when considering biopsy since two recent case histories have revealed that shortly after a biopsy was performed each patient having been previously in good health generalised symptoms typical of the disseminated form of histoplasmosis arose followed by death a few months later The diagnosis was confirmed post mortem and it appears possible that the organism was disseminated into the blood stream when the biopsy was performed

Prognosis—In the past histoplasmosis was often considered to be an almost invariably fatal disease More recent knowledge indicates that the mortality is probably extremely low since it is considered reasonable to assume that a positive histoplasmin skin test indicates past invasion of the tissues of some part of the body by the fungus and such positive reactions have been obtained from several millions of persons in the United States Such persons often have scattered calcified areas in the lungs such as are found after histoplasmosis It is thought therefore that the majority of infections are overcome without any noticeable disturbance of health or the disease passes unrecognised as the illness is of short duration and spontaneous recovery ensues

Where the diagnosis is made during the clinical course of the disease it may be

tissue Superficial or deep ulcers may be seen in the small or large intestine and nodules have been found in the submucosa and deeper layers of the intestinal wall Caseation of the suprarenal glands may cause almost total destruction of glandular tissue, and a recent review of 103 fatal cases of histoplasmosis revealed that 35 per cent were found post mortem to have some damage to suprarenal glands Infections commencing in the mouth pharynx or larynx show localised necrotic ulcerations and enlargement of the regional lymph nodes

In the benign pulmonary infections multiple small discrete, fibrotic nodules may be found in any part of the lungs and early enlargement of the tracheo bronchial and hilar lymphatic glands is usual The central portions of the nodules become caseous and later calcify these residual lesions are often seen in a routine radiograph taken months or years after the infection occurred When the lung is involved in the disseminated form of the disease there is usually an extensive bilateral inter stitial pneumonitis in the early stage of the illness with diffuse or localised areas of consolidation At times abscess formation occurs which may be followed by cavita tion Where healing takes place fibrosis with contraction often causes deformity of a section or lobe, and a clinical diagnosis of chronic tuberculosis or bronchiectasis is not an uncommon error where it occurs near the lung roots it may be mistaken for a bronchogenic carcinoma Occasionally the infection is confined to the medi astinal lymph nodes and a picture almost indistinguishable from Boeck s sarcoid or lymphoma is presented

Clinical Features —(i) *Disseminated histoplasmosis* —This may be an acute and rapidly fatal illness and this form is most common in infants, in the aged or in those debilitated by tuberculosis or malignant disease More commonly it runs a sub acute course the illness extending over many months with a fatal termination in most instances although arrest of the disease and ultimate recovery have been recorded a number of times

There is no characteristic clinical picture Common early features are debility, loss of weight low grade fever sweating joint and muscle pains abdominal dis comfort and diarrhœa Leucopenia and progressive anæmia are almost invariable and enlargement of the liver and spleen are usually found Involvement of the suprarenal glands may destroy so much glandular tissue that Addison s disease results and histoplasmosis should always be excluded when such a diagnosis is made If the infection spreads to the lung it will usually give rise to a pneumonitis with an abrupt onset accompanied by fever around 103 to 104° F but seldom any clinical features to distinguish it from a viral pneumonia Symptoms may be limited to occasional chest pain and a dry unproductive cough The physical signs are seldom of any diagnostic value By contrast a radiograph shows an extensive bilateral inter stitial pneumonitis miliary or patchy together with enlarged hilar lymph nodes The acute stage lasts for 7 to 10 days followed by gradual subsidence The radio graphic signs however do not reach their maximum for 2 weeks after 6 weeks a fine nodular fibrosis may be seen and after 3 months nothing abnormal may be detected More often though, when recovery takes place contraction follows the fibrosis with marked deformity of the affected lung section

(ii) *Primary pulmonary histoplasmosis* —This form is very often asymptomatic it may cause mild catarrhal symptoms and malaise and suggest influenza or bronchitis Spontaneous recovery is the rule and the disease is seldom recognised before this has taken place It may be months or years before the residual lesions are seen in a radiograph as the examination is nearly always made either as a routine or for some other condition

Laboratory Findings —The fungus may usually be found in the cytoplasm of the reticulo endothelial cells and in the macrophage cells in the form of round or oval yeast like bodies varying from 2μ to 4μ in diameter Smears stained by Giemsa s method show chromatin irregularly condensed within a refractile capsule The

TOXOPLASMOSIS

Definition —An uncommon disease of man and animals of world wide distribution caused by a small protozoon *Toxoplasma gondii* which may be transmitted to the foetus *in utero* by an infected mother or acquired by some means as yet unknown in childhood or in adult life The majority of infections probably pass unnoticed but the parasite may give rise to a wide variety of symptoms and signs of differing severity and variable duration depending partly upon the age of the person when infected which tend to be so grouped that four main clinical types of illness may be recognised

1 CONGENITAL —This form is characterised by encephalomyelitis cerebral calcification hydrocephalus and choroidoretinitis with symptoms either apparent at birth or appearing soon afterwards

2 ACQUIRED —

(i) *Cerebrospinal*—most frequent in children in whom the most typical manifestations are those of an acute meningoencephalitis

(ii) *Lymphatic*—characterised by the enlargement of one or more groups of lymphatic glands with at times fever of several weeks duration and marked constitutional disturbance

(iii) *Exanthematous*—the form most frequently found in adults presenting as an acute febrile illness with a widespread maculo papular rash a diffuse interstitial pneumonitis myocarditis and at times meningoencephalitis

(iv) *Latent*—where infection by *T gondii* gives rise to no symptoms or signs of the disease and diagnosis can only be made by means of laboratory tests Latent infections are found only in adults and are probably always acquired after the age of childhood

Ætiology —The causal organism was first discovered in 1908 in a small North African rodent the gondi (*ctenodactylus gundi*) and it was named *Toxoplasma gondii* Nicolle and Manceaux It was thought to be a protozoon and was classified as one of the sporozoa but there is still much doubt about its true position Although many species have since been described *T gondii* is considered the only species occurring in man and animals all other forms described being considered strains of a single species since both morphologically and immunologically they all appear to be identical

T gondii is an intracellular parasite found usually in the endothelial cells the mononuclear leucocytes or the tissue cells Free living forms may also be found in the tissue fluids of the host In this free extracellular form the parasite is a slender crescent shaped organism with one end rounded and the other pointed measuring from 4μ to 6μ in length its breadth being around 2μ Intracellular forms often lose the crescent shape becoming pear shaped oval or rounded when they may readily be confused with *Leishmania* In dry films stained by Wright s or Giemsa s methods the cytoplasm is blue the granular nucleus which is single and fills about one quarter of the cell stains a reddish purple and will be seen near the rounded extremity whilst towards the pointed end there is a small deeply staining red granule the paranuclear body The parasite multiplies by longitudinal fission within the endothelial and tissue cells of its host With virulent strains these cells rupture early releasing the parasites which then invade fresh cells thus enabling the parasite to multiply extremely rapidly though in the light of present knowledge with doubtful benefit to itself since it may result in an overwhelming and rapidly fatal infection of its host With less virulent strains the cells often remain intact allowing reproduction to continue until they become greatly distended by 80 or more parasites

said that in primary pulmonary histoplasmosis, recovery nearly always occurs spontaneously and the prognosis is excellent Localised infections are more serious and run a much more prolonged course They usually progress by localised extension, and unless the disease is arrested they tend to be ultimately fatal There are, however a number of records where the disease has continued for many years without any serious disturbance of health to the persons affected

More than one quarter of the fatal illnesses occur in infants under 1 year of age In these the disease is nearly always in the disseminated form, and up to the present time it has been found that over two thirds of all cases of disseminated histoplasmosis have a fatal termination

Treatment—It is fortunate that the great majority of cases recover unaided since despite favourable initial reports on a number of new compounds there is not yet sufficient evidence to consider any of them curative

Most of the established antibiotics and sulphonamides have been tried and they have all been reported to be ineffective although recent laboratory trials have shown that several sulphonamide compounds do have a pronounced action on *Histoplasma* and are capable of overcoming infections in mice previously innoculated with lethal doses of *H capsulatum* Sulphanilyl thiourea is by far the most active of the many compounds tested possibly because unlike most of the other sulphonamides it is only partially inactivated by *p* aminobenzoic acid The yeast phase of the fungus is far more sensitive to the drug than is the mycelial phase and this may explain its efficacy in histoplasmosis in mice which is usually a very acute and rapidly fatal infection In the more chronic infections, common in humans the mycelial phase of the fungus may predominate, making its eradication much more difficult Further clinical trials of sulphonamides seem necessary

The use of cortisone and related compounds should be avoided in histoplasmosis as it has been found that the initial improvement that often occurs following their administration is temporary and rapid extension of the disease often follows When the suprarenal glands have sustained such severe damage that Addisonian crises occur cortisone will be necessary to tide over the crisis and to prevent their recurrence small maintenance doses together possibly with DOCA should be given

Ethyl vanillate received favourable reports when first used but later trials failed to confirm its value Stilbamidine and more recently 2 hydroxy stilbamidine have been used, and they have appeared to have a favourable influence upon the course of the disease although the response to their administration is somewhat uncertain

Two drugs still undergoing laboratory trials have given encouraging results combining powerful anti fungal properties with low toxicity for many different species of animal One nystatin (fungicidin) is an antibiotic which has been marketed under the trade name of Mycostatin In laboratory animals it has proved to be highly effective in all forms of infection whether fulminating moderately acute or chronic and the therapeutic doses have not been toxic In contradistinction to sulphanilyl thiourea nystatin is more active against the mycelial phase of *H capsulatum* If the preliminary reports on these two drugs are substantiated treatment with a combination of the two may prove to be highly effective

The other drug MRD 112 (β diethylaminoethyl fencholate) also has marked anti fungal properties combined with a low toxicity In human infections it has been given by intravenous injection commencing with a dose of 50 mg daily later increased to 150 mg daily the duration of treatment being 24 to 28 days The higher dose may cause drowsiness at first but clinical improvement has been apparent soon after the commencement of treatment although radiographic studies have shown very little change in the lungs throughout this period It should however be remembered that in cases with an acute pneumonitis due to histoplasmosis the radiographic signs in the lung do not usually reach their maximum for 2 to 3 weeks after the onset although subsidence of the infection often commences after 7 to 10 days

it Neither is it always easy to reproduce the disease in animals and it has been found that if dogs are inoculated with the parasite even with highly virulent strains only the younger pups develop the acute form of the disease the older dogs remaining quite free from all signs of infection Recently dogs have been suggested as a probable source of human infection as not only has acute toxoplasmosis occurred in the owners of dogs harbouring *T gondii* but neutralising antibodies have been demonstrated in the blood of more than one third of the owners of dogs from whom the parasite has been recovered Whatever significance may be attached to such findings it should be remembered that as there is usually a very close association between dogs and their owners it is equally probable that both could have been infected simultaneously from the same source

Until the life cycle of *T gondii* is known it seems unlikely that the many problems concerning the epidemiology of toxoplasmosis will be solved Of the many prevailing surmises on the mode of entry of the parasite into the human body the majority of those who have studied the disease consider the three following routes the most probable

(i) the gastro intestinal tract following the ingestion of infected food
(ii) the respiratory tract by inhalation of droplets containing the parasite
(iii) the skin and blood stream following the bite of an infected arthropod

It is not yet known whether the vegetative forms of *Toxoplasma* are as vulnerable to human gastric juice as they are to that of experimental animals nor is it known how resistant the pseudocysts are to storage desiccation cold or heat Since they occur quite frequently in the muscles of animals used as food the eating of raw or insufficiently cooked meat would seem a likely source of infection The pseudocysts have also been found in the ovaries of hens it is therefore possible that eggs could convey the infection Recently toxoplasmosis has been recognised in cattle and the disease has been transmitted to calves both congenitally and in the milk In nearly all rural areas in Great Britain unpasteurised milk is the only form available and this could well provide another source of infection should the disease become common in cattle

It has already been mentioned that *Toxoplasma* are present in the bronchioles and probably in the sputum of human cases of toxoplasmosis with pneumonitis and this is true of domestic animals with clinical evidence of the disease Moreover respiratory symptoms are a much more prominent feature of the disease in most animals than they are in man and thus those looking after such sick animals might well become infected by the inhalation of infected droplets and also possibly through the con junctiva since animals have been infected by this route

Apart from the bites of infected insects infection *via* the skin is also possible through the handling of infected tissues as it is known that *Toxoplasma* can penetrate closely shaved skin and it is therefore not improbable that some human infections may be caused by the parasite entering through cracks and small abrasions in the skin This would certainly explain the increased proportion of positive serological reactions that has already been observed in veterinary surgeons slaughterhouse workers and in particular in those handling rabbits

Pathology—Following infection the parasites are distributed throughout the body by the blood stream and become established in the cells of the reticulo endothelial system and also in the parenchymal cells Localisation occurs in many organs more often in the brain lung liver or spleen parasites often being found also in the kidney suprarenal glands bone marrow and lymph nodes Muscle fibres are also invaded in particular those of the heart as well as the skeletal muscles They may also be found within phagocytic cells and living free in the intracellular fluids of the affected organs

The typical lesions are small focal areas of necrosis surrounded by a zone of

their nuclei are then extruded, and the hypertrophied cyst like structures that remain packed with parasites are known as pseudocysts Within them the parasites seem to be in a resting or inactive stage, causing little tissue damage or cellular reaction the cyst wall probably affording protection from any circulating antibodies thereby enabling a chronic infection to become established

T gondii can be cultivated in the laboratory if living tissue cells are used It propagates most readily on the chorio allantoic membrane of the developing chick embryo at 35° to 37 C if protected from bacterial contamination and dehydration The embryo usually dies between the seventh and tenth days

Epidemiology —*Toxoplasma gondii* has been found in many species of mammals and birds and also in certain reptiles The first authenticated report of human infection was made in 1923 since when human infections have been recorded in many European countries, including Great Britain in the Middle East Ceylon North Central and South America, Australia and Hawaii The incidence of toxoplasmosis in man is not known yet, but subclinical infections are probably much more frequent than it is generally realised Recent surveys using serological tests have shown that positive reactions, suggesting a past infection may be given by from 10 to 50 per cent of the adult population in many areas Such figures should however be treated with caution since doubt has been cast on the validity of some of the tests used it having been found that they are not specific for *T gondii*

Very little is known about the transmission of the parasite to humans or of the source whence it originates, though it is thought to be conveyed from animal reservoirs by some means still awaiting discovery Rodents and dogs in particular are thought to be a possible source of infection

Neonatal infections appear to be conveyed transplacentally to the fœtus from an infected mother who almost invariably remains free from any symptoms of the disease herself If the infection is acquired early in pregnancy by the mother, abortion will probably result or if the pregnancy continues the fœtus will be so extensively damaged that it will be stillborn Infection late in pregnancy may result in the infant being free from any signs of the disease at birth and several weeks or even 2 or 3 months may elapse before signs and symptoms appear Later offspring from such mothers with one possible exception have never yet been born with toxoplasmosis It seems probable that if the mother became infected during the puerperium the disease could be transmitted to the infant if it was breast fed, as lactating laboratory mice have conveyed the parasite to their offspring in the milk

Laboratory workers handling *Toxoplasma* have several times acquired very severe or fatal infections though by what means remains unknown

Direct case to case infection seems improbable since laboratory animals have hardly ever been known to infect their cage mates even in experimental conditions planned to achieve it In the adult form of the disease with a diffuse pneumonitis the parasites are often plentiful in the secretions in the small bronchioles and in such cases droplet infection would seem a possibility

Nearly all warm blooded species of animals can be infected experimentally and the parasite has been transmitted in the laboratory

(i) by feeding to animals either tissues containing it or food contaminated with fæces in which it is present
(ii) by inoculation by almost any of the usual routes intranasal intravenous intraperitoneal intracerebral or subcutaneous
(iii) by direct penetration of closely shaved skin by the parasite,
(iv) by penetration of the mucous membrane of the vagina and the conjunctiva

Infection of animals by the alimentary route is not always easy as the gastric juice tends to kill the vegetative forms of *Toxoplasma* The pseudocysts are more resistant and the feeding of tissues containing them has proved to be the easiest way of achieving

The signs secondary to encephalomyelitis most frequently found are muscular twitchings and convulsions stiffness of the neck paraplegia respiratory weakness and cyanosis which at times may be due to an interstitial pneumonitis vomiting and diarrhœa Hydrocephalus develops in the majority of infected infants and rapid enlargement of the head may occur At times when there is early and extensive cerebral damage microcephaly may be found The cerebral lesions become calcified if the infant survives long enough and may later give rise to Jacksonian convulsions and the majority of infants who survive for a number of years are nearly always mentally deficient

The ocular findings most frequently include microphthalmia, the small eyes being in striking contrast to the enlarged head nystagmus which may result either from poor fixation due to choroidoretinitis or from the lesions in the central nervous system vitreous opacities and choroidoretinitis The lesions are nearly always bilateral and cause blindness or very severe impairment of vision in those infants who survive The majority of infants however die within the first few weeks of life

2 ACQUIRED TOXOPLASMOSIS

(i) *Cerebrospinal*—In the earlier accounts of toxoplasmosis this form of the disease was usually considered to be not only the invariable manifestation of infection in children but also to be confined solely to them Meningo encephalitis has in recent years been reported many times in adults with the disease but it is seldom the initial feature of the attack usually occurring as a complication of the exanthematous form towards the end of the first or second week of the illness not infrequently after the acute stage has subsided and recovery appears to have commenced

The cerebrospinal form is probably still found more frequently in children in whom it tends to be the predominant feature of the illness The onset is marked by fever very severe headache vomiting and delirium Convulsions often occur a day or two later and the picture presented may suggest a brain tumour Deafness is often found and very occasionally choroidoretinitis has been recorded but it is not a constant feature as in the congenital infections The attacks are frequently severe and often rapidly fatal with death following within a few days of the onset Some infections run a more chronic course but not necessarily with a more favourable outcome since death may occur several weeks after the commencement of the illness Complete recovery is however by no means uncommon without the development of any sequelæ even when the attack has been exceedingly severe

(ii) *Lymphatic*—Some of the earlier accounts of toxoplasmosis mentioned that a generalised enlargement of lymphatic glands was occasionally observed but it is only in recent years that the lymphatic form has been recognised as a clinical type that occurs without any of the other manifestations of the disease It has been stated quite recently that probably the commonest manifestation of acquired toxoplasmosis in man yet known is a lymphadenitis resembling glandular fever The total number of cases of this form of infection reported to date does not yet seem large enough to confirm the above statement Although the lymphatic form is not usually described as occurring predominantly in children nearly all the recorded cases have been found between the ages of 5 and 15 years

As with most infectious illnesses there is a fairly wide range in the severity of the attack and there seems to be no practical advantage in adopting the classification which divides this form into three main clinical groups since they do not appear to differ except in severity

A proportion of these cases have a sudden febrile onset often with a rigor and fatigue is a common premonitory symptom which precedes the onset by several days The fever usually rises rapidly to about 104 F and is frequently accompanied by catarrhal symptoms cough headache and pain in the back At times the throat is

inflammation containing lymphocytes mononuclear and plasma cells Hypertrophied cells distended with parasites the so called pseudocysts are often seen Serous exudates are commonly found in the various body cavities

In congenital cases lesions predominate in the brain, spinal cord, retina and choroid Inflammation often extends to the ependyma causing ventricular block and hydrocephalus As well as the typical necrotic foci minute granulomata are also found in the brain which calcify if the affected infant survives long enough The lesions in the central nervous system are not very marked and often sections must be searched with the greatest diligence before they are seen.

In the acquired adult infections which usually pass unnoticed the lesions are often found accidentally Rarely there is a widespread dissemination of the parasite with lesions throughout the body though more often the predominant feature is an interstitial pneumonitis with thickening of the alveolar walls and infiltrations of giant and plasma cells There may also be scattered areas of purulent bronchiolitis Inflammatory and necrotic areas are also quite frequently found in the liver, spleen and heart muscle and encephalitis has occurred in several adult cases, though it is seldom as predominant a feature as in congenital infections or in the acquired infections of children

Clinical Features —As knowledge of toxoplasmosis increases and as more clinical reports become available so does it appear that the sharply demarcated clinical syndromes that were described in the earlier accounts of the disease do not in reality exist apart from the fairly clear cut distinction between congenital and acquired infections

Whilst it is still true that there is a preponderance of certain clinical features in children suffering from toxoplasmosis, with others appearing with greater frequency in adults, there no longer seem to be any clinical manifestations of acquired toxoplasmosis that are sufficiently exclusive to one or other age group to justify the old subdivision into acquired infections—in children, and acquired infections in adults

I CONGENITAL TOXOPLASMOSIS

Acute infections with widespread dissemination of the parasites and necrotic lesions in many organs in particular the lungs, the heart liver spleen kidney supra renal glands and lymphatic glands have been described but occur very infrequently in congenital toxoplasmosis Subacute infection is the common form, with predominating neurological symptoms which may be noted at birth or shortly afterwards If the fœtus is infected very early in pregnancy the disease will reach an advanced stage *in utero* and cases have been recorded where the pregnancy having continued to term was followed by an obstructed labour owing to the development of hydrocephalus in the fœtus

In the typical subacute congenital infection the symptoms and signs may be subdivided into

(i) those due to the presence of parasites within the body these may be called primary symptoms and signs
(ii) those secondary to the principal lesions caused by the parasite namely encephalomyelitis and choroidoretinitis

The common primary signs are fever with a fluctuating temperature which may at times be subnormal jaundice which has been described in about one third of all congenital cases purpura which occurs infrequently and a maculo papular rash which is extremely rare Anæmia and leucocytosis with an absolute increase in monocytes and lymphocytes, are found in about one half of all cases and the liver and spleen are not infrequently enlarged

much more constant In several proved cases eosinophils have been raised to from 14 to 20 per cent of the differential count

(ii) *Cerebrospinal fluid* —This is often xanthochromic in cases with encephalo myelitis Protein usually considerably increased, the increase being relatively greater than that of the cells Sugar normal in amount or slightly decreased Cells leucocytes are often present in large numbers with a very considerable range an average or usual figure being around 500 per c mm though counts of 60 and 1600 are often recorded erythrocytes are usually present but in lesser numbers

Definitive Diagnosis —The definitive diagnosis of toxoplasmosis by the direct isolation of *T gondii* from the patient is frequently not possible and therefore in direct methods are also employed and provided that a full range of investigations is carried out with consistent findings a diagnosis of toxoplasmosis may still be established with reasonable certainty

(i) *Morphological Identification of Toxoplasma* —During the acute stage of the infection the parasite may sometimes be found in stained smears of bone marrow in material obtained by splenic puncture or in the centrifuged deposits of exudates cerebrospinal and ventricular fluids Fresh cover slip preparations should also be examined Smears should likewise be made from a portion of any tissues removed at biopsy or autopsy and these should be stained with Giemsa the other portions should be fixed and thin sections made which should be stained with hæmatoxylin and eosin and then very carefully examined with an oil immersion lens The para sites in the pseudocyst form are those most easily recognised after a little experience

(ii) *Biological Identification of Toxoplasma* —Material obtained from a suspected case of toxoplasmosis should be inoculated into laboratory animals which must be free from naturally occurring infection in themselves Mice hamsters and guinea pigs are the most satisfactory animals and at least six mice and two guinea pigs must be used before any reliance can be placed on the test Similar material to that used for making stained smears should be injected intracerebrally into the mice and intra peritoneally into the guinea pigs The animals should be watched for signs of illness if after a month all have remained well, passage to another group of animals should be undertaken by the inoculation of tissues from one half of the first group Where illness develops exudates should be carefully examined and if *Toxoplasma* are not found part of these fluids should be inoculated into other animals Smears should be made and carefully examined from the brain lung liver spleen and the peritoneal lining of any animals that die The parasite may be found after the primary inocula tion and it is frequently isolated after the first passage For practical purposes not more than three passages should be performed since it is quite exceptional for the parasite to be recovered if the first three passages have proved to be fruitless

Direct demonstration of the parasites has only been possible in about one half of the total number of human cases so far described

Indirect Methods of Diagnosis —(i) *Complement Fixation Test* —An antigen derived from chick embryo cultures should be employed and the test serum should be exam ined within 24 hours of taking the blood as complement fixing activity may develop spontaneously after a longer period Complement fixing antibodies develop 3 to 4 weeks after infection occurs and may persist for several years in fairly high titre although they often disappear during convalescence Some 10 per cent of healthy adults give a positive result with this test but a titre of over 1 8 suggests a recent infection

(ii) *Neutralising Antibody Test* —Infection with *T gondii* leads to the formation of antibodies in the blood which may persist for many years after recovery They may be demonstrated by their ability to prevent infection of the chick embryo with *Toxoplasma* or the development of skin reactions in the rabbit Although all human

sore and there may be abdominal discomfort and diarrhœa These symptoms and the fever nearly always precede the glandular enlargement and it may be a week or more before the enlarged glands are first observed The fever usually last for 2 to 3 weeks occasionally for a few days only whilst it has at times in adult infections been pro longed for 6 to 7 weeks with a high initial fever of about 105° F, slowly subsiding to about 102° F some ten days from the onset after which it may fluctuate between 100° F and 101° F for 2 to 3 weeks before slowly returning to normal Although there are no complications and recovery invariably follows the febrile cases often require a prolonged convalescence, fatigue being a very prominent feature for 3 or 4 months following an attack

A large number of cases are afebrile and free from any symptoms apart from at times some initial tenderness in the region of the enlarged glands the general health remains unaffected by the infection Others remain unaware even of the enlarged glands which are found during some routine examination

The characteristic feature of this form of toxoplasmosis whatever degree of severity it may assume is enlargement of one or more groups of lymphatic glands Those most frequently affected are the cervical suboccipital axillary and inguinal groups A radiograph of the chest may also reveal enlargement of the hilar glands Enlargement of the cervical glands is fairly constant and they are nearly always the first glands to become affected other groups becoming enlarged after an interval of several days or even 1 to 2 weeks The glands are usually firm discrete and vary in size from that of a hazelnut to that of a walnut They are usually painless though there may be some initial tenderness during the first week or two of the illness There is no inflammation of the skin overlying the glands and suppuration does not occur

Another very characteristic feature of all cases whether febrile or afebrile is the persistence of the glandular enlargement enlarged lymph nodes usually can be found 6 to 9 months after the onset of the attack

(*iii*) *Exanthematous* —Although many clinical forms have been described in adults the most typical is an acute febrile illness of sudden onset sometimes marked by rigors soon followed by the appearance of a generalised maculo papular rash which is absent from the palms of the hands and the soles of the feet and which closely re sembles the rash of typhus or Rocky Mountain spotted fever There may be a disseminated myositis giving rise to severe aching pain in the muscles or at times to myocarditis when the heart muscle is involved The outstanding feature however is a diffuse interstitial pneumonitis resembling an atypical virus pneumonia which frequently runs a rapid course with severe dyspnœa cyanosis and respiratory failure Enlargement of the liver and spleen will be found in a few cases and encephalitis has recently been a feature of several acute cases in adults

Diagnosis —*Clinical Diagnosis* —Even presumptive evidence of *Toxoplasma* infec tion is rarely obtainable on clinical findings alone except in infants A combination of convulsions hydrocephalus or microcephaly choroidoretinitis and calcified areas in the brain seen in a radiograph strongly suggests toxoplasmosis when found in infancy and in older children a similar picture together with blindness or serious impairment of vision and mental deficiency makes a similar diagnosis equally prob able In adults clinical diagnosis is extremely difficult and it is more likely to be considered under the differential diagnosis of an unidentified infection than as a probable diagnosis by itself

Laboratory findings —The usual routine laboratory investigations give little help in toxoplasmosis (i) *Blood* —Anæmia of moderate degree is usual particularly in infants though the hæmoglobin is seldom less than 12 3 g or the red cell count below 4 million The leucocytes are usually slightly increased in numbers from 9000 to 12 000 being a common finding with a considerable increase in lymphocytes and monocytes in many cases the increase in monocytes being of lesser degree but

INDEX

limited to a few reports but it appears to be the most effective remedy at present available particularly when combined with sulphadiazine The effect of this combination appears to be synergistic since it has been found to be six times greater than would be expected if it was purely additive The best results are given by a combination of 22 per cent pyrimethamine to 78 per cent sulphadiazine The most effective doses of pyrimethamine are considerably higher than those normally used in practice the lower dosage being adopted on account of the risk of toxic effects Treatment is usually commenced with a small dose of 25 mg daily which is increased after 3 or 4 days to 50 mg daily Treatment is usually continued for 10 to 14 days the total dosage of pyrimethamine being from 500 to 700 mg In one series of 13 cases receiving this treatment one patient was left with a psychosis the cause being unknown complete recovery was recorded for the remainder Pyrimethamine has also been tried in cases of uveitis where serological tests suggested toxoplasmosis to be a possible cause The results so far have been rather indecisive but further trials are still in progress
